Taking a closer look at “language in use” in classrooms is particularly important for both teachers and students. Precisely because they are learning the content for the first time, students are unlikely to be familiar with the discourses and language patterns of the disciplines that frame the subject areas of secondary school. What’s more, students rarely possess the disciplinary, topic, and world knowledge necessary to draw inferences and engage in strategic reading that employs language cues as a guide. Consequently, their facility with reading and content area learning is dependent on teacher scaffolding of knowledge construction and instruction in disciplinary discourses and language patterns. Unfortunately, although content area teachers are generally skilled readers in their subject areas, they may take for granted or be unfamiliar with the linguistic and discursive themes of their particular subject areas (Fang & Schleppegrell, 2008; Rackley & Birdyshaw, 2008; Shanahan & Shanahan, 2008). In particular, many teachers fail to recognize the deep level of knowledge necessary to use language cues to make inferences among ideas in a text and have little understanding of how language works to cue readers; as a result, many secondary teachers often assume that students can simply take in content as they read.

This gap between students’ knowledge and abilities and what teachers teach is located in a context where both written and oral texts are often crucial components in the development of content area knowledge. All classroom texts and activities, for example, are constructed through language, both oral and written, and secondary school classrooms are even more highly dependent on print—often read independently—than are elementary classrooms (Carnegie, 2010). Attending to the linguistic features of content area reading and discourse provides one useful tool for the consideration and development of content learning and reading comprehension. When teachers can recognize these features of their content areas and teach them explicitly to students, their students will be better able to unlock these codes and learn content more effectively. What, then, does one need to know to begin to open up the language codes of the content areas and what does a focus on language contribute to the study of content area reading?

Reading is a cognitive and sociocultural process, involving internal mental processes mediated by external social interactions and cultural practices. Specifically, reading occurs as a complex interaction between reader, text, and activity, all set in a range of contexts (Rumelhart, 1984; Snow, 2002). The reader brings language facility, knowledge, and motivation to the interaction; the text brings structure, varying levels of complexity, genre, topic,

a point of view, and other such characteristics; and the activity provides a purpose and goals, environmental conditions, resources, and spatial and temporal frames for the act of reading (Anderson & Pearson, 1984; Tierney & Pierson, 1992; Moje, Dillon, & O'Brien, 2000; Snow, 2002; Moje, 2006).

Unfortunately, texts, students, and subject-matter classrooms are not stable, uniform entities, thus making the instructional task of teaching content area reading extraordinarily complex. Secondary school teachers might see between 80 and 180 students in a given day, depending on teaching load. Those students might hail from different communities, social classes, and racial or ethnic backgrounds. In addition, students who enter school with language backgrounds that do not closely match the dominant academic language of the country may have more difficulty with content area texts than do students whose language more closely matches the standard form. Therefore, a focus on language can be particularly useful to students because it can help them recognize the genres and text structures common to the discipline of that content area.

Like students, subject areas and classes can be diverse. Subject areas can be broken down into subfields of a given discipline or might represent different content standards. The timing of classes and schedules varies. Different kinds of resources are available across different disciplinary areas. And secondary school texts can vary along many dimensions, both within and across the content areas. Acknowledging and examining differences across students, subject matters, and texts is thus an important first step in linguistic research on content area reading. Given the scope of this essay, however, we cannot address each of these dimensions of content area reading in relation to linguistic study. Consequently, in what follows, we foreground the question of text and language differences by disciplinary area, with issues related to diversity of student language proficiencies and broader contexts of the secondary school and community taking the background. It is important to note, however, that students and broader contexts should never fade entirely from view, given the model that posits the act of reading as the *intersection* of each of these domains. That said, we focus on texts and classroom discourse to allow for a close analysis of the role of language in content area reading.

Types of Texts in Secondary Schooling

Over the span of even one day, students in upper elementary and secondary school classrooms will encounter a wide array of texts. In English classes students might read literary text, whereas in mathematics classes students are likely to read mathematical problems, proofs, or theorems, sometimes in textbooks, but often as embedded in teacher lecture notes. The same students in natural science (i.e., physics, biology, chemistry, earth sciences) classrooms might encounter information in print and tables, via textbooks or Internet sites; but in social science (i.e., history, economics, civics) classrooms they might be asked to read lengthy textbook passages connected to maps and charts, together with secondary sources and primary documents, such as speeches, diaries, and newspaper articles. With these variations in types of texts by subject area come variations in the dimensions and demands of texts.

Equally important, the features of those different texts vary *within* subject-matter areas and disciplines, especially as students progress through levels of schooling. Within the natural science subject areas of school a student might encounter a science textbook, lab manual, report, newspaper article, science magazine, or Internet passages that include definitions, moving images, and three-dimensional representations. The typical science textbook at the lower grades might be written in a style that varies from narrative to exposition, whereas the upper grades science textbook generally leans toward heavy exposition, with a smattering of narrative assumed to draw the reader in (Santa & Alvermann,

1991). By contrast, the genres of disciplinary scientific writing, for example in the form of lab or research reports, have clear standards for warrant drawn from empirical investigation and often employ particular discursive features to produce a distanced, objective style and tone. The phrase “It has been asserted,” for example, when compared to the phrase “Halliday asserted,” would be considered *low modality*, or a backgrounding of the actor to indicate uncertainty or open possibility. Low modality and other similar linguistic devices are key tools for hedging hypothetical statements or tentative conclusions (Myers, 1989; Lemke, 1990; Yore, Hand, & Prain, 2002).

Turning to the social sciences, students in a history class might encounter a history textbook, documents taken from archives (often referred to as “primary sources”), historical magazine articles, museum documents, and Internet passages (Bain, 2006). As in the natural sciences, Internet passages may be replete with hypertextual links that define terms or explain relationships among key actors or events in history, and in both cases, as well as in the English-language arts and mathematics, another type of text plays an important role: teacher lecture notes (Dillon, O’Brien, & Volkmann, 2001). Especially important is the question of how teacher talk matches or contrasts with the discourse of the disciplines (Lemke, 1990; Moje, 1997; Moje, Collazo, Carrillo, & Marx, 2001). One approach to discussing content area reading, then, is to acknowledge the role that multiple types of texts play in understanding how students learn to read in different disciplines, rather than focusing primarily on textbook passages, which are rarely the key text of secondary learning even if they are the most prominent. A second is to ask what differences there are among texts, both within and across subject areas, in terms of how content, voice and audience, and textual structure affect students’ construction of meaning while reading.

Linguistic Differences Within and Across Subject Areas

A consideration of these differences leads to a focus on language in use and highlights, for example, how a first-person historical narrative is different from a fictional short story, or how a mathematics word problem is different in its language use and structure from the description of a scientific phenomenon. Halliday (1996) analyzed disciplinary discourse and texts in a way that fits neatly within a sociocultural model of reading as the interaction of text, reader, activity, and context. Halliday’s focus on the functions of language in use and on the different meaning dimensions of texts offered tools for researchers and teachers alike to examine how the language of disciplinary texts presents challenges to students because the language itself functions as a way to communicate the epistemology—or the nature of knowledge and thought—of the discipline. For example, Halliday argued that science texts displayed particular patterns in grammar and organization. As in history, when developing a scientific argument scientific processes are often nominalized (changed from verb to noun phrases, e.g., *react* to *reaction*), and arguments are carried forward by thematizing, or making the process the subject of a new sentence, in order to carry the process further into its next step.

A focus on language in use highlights how these academic forms of language and text are different linguistically from the everyday speech and language of students. If students lack understanding of academic linguistic differences and expectations, then they may encounter difficulty in both reading and writing following content area norms. Writing in science generally employs a different tone and register from writing in literature and language arts, for example, and problems in navigating these differences become visible when students write research reports in history or science using informal language or syntax that places their own views in high modality. Students may transfer one type of genre often used in literature classes, the personal narrative, with its more informal register and narrative structure, to texts which should be more formal and have more complex

structures with claims and warrants, particularly if teachers are not attentive to the ways *they* talk about texts they want students to read and produce (Moje et al., 2001). If, however, students have never been explicitly taught these structures and if they have not had practice with the language used to create these relationships, then such transfer may be difficult.

Studies of Content Area Classroom Talk and Texts

Lemke (1990) drew from Halliday to focus on the thematic patterns in language used in science classroom talk. Lemke argued that relationships among scientific concepts covered in the classes were continually built and reinforced through talk. In his analysis of classroom conversations, he noted patterns of semantic relationships used to convey science knowledge, including the construction of cause-and-effect explanations, as well as the use of evidence to support scientific conclusions. Lemke found that teachers used language flexibly, finding different ways to communicate these patterns, often using everyday language to develop or explain scientific concepts (see Moje et al., 2001). In this way, teachers built upon students' existing concepts and the language they used to represent those concepts so that they could later develop more scientific conceptualizations and language practices. Lemke also demonstrated, however, that without careful attention to how language was used in the discussion of scientific concepts, teachers at times inadvertently communicated or reinforced misconceptions by substituting everyday terms for more precise scientific terms, thus miscommunicating the underlying scientific themes.

Discursive analyses of content area classrooms have also revealed epistemological assumptions of teachers and students that have implications for how they make sense of classroom texts. Brown, Reveles, and Kelly (2005), for example, analyzed the ways that science teachers' classroom talk positions students as certain kinds of people (i.e., as having particular science and student identities; see Barton, Tan, & Rivet, 2008). Similarly, Moje's (1997) analysis of one chemistry teacher's talk showed how the teacher positioned students as demonstrators of knowledge and herself as evaluator of knowledge, with classroom texts (including teacher lecture notes) the repositories of accurate and immutable science knowledge. This positioning developed as a result of classroom talk, despite the chemistry teacher's firm belief that scientific investigation was a process of discovery rather than a transmission of information. Similarly, Bain's (2006) analysis of what his high school history students assumed about the authority of textbooks demonstrated that students enter secondary school classrooms with assumptions about the nature of knowledge, the authoritative role of texts, and their own positions and identities as learners in relation to those texts. Only with skillful and explicit attention to written texts were these assumptions challenged in ways that allowed the students to read and think critically about historical concepts (see Bigelow, 1989).

Fang and Schleppegrell (2008), working within the framework of Halliday's (1996) functional linguistics, identified specific features of academic language in content area textbooks that have an impact on student reading: (a) the presence of multiple semiotic systems; (b) differing expectations for organization related to genre, register, and structure; (c) density and abstraction; and (d) technicality and authoritative stance. In one page of a textbook, for example, students may encounter various semiotic, or symbolic, representations of meaning. They may read text and then see a photograph with a caption, a table with numeric information, and then a cartoon. Each type of information requires a different set of interpretive tools. At the secondary school level, many different ideas may be packed into a small amount of written text and abstract concepts are often not unpacked.

Moreover, the vocabulary used with respect to these concepts differs as well. A "product" in math class is not the same thing as a "product" in economics. Mathematics vocabulary

often has an accompanying set of symbols that can be represented in different ways. The term “divided into,” for example, can be written in several different ways and represented with more than one symbol. Technical terms are commonplace, but may be more easily identified in science when compared to terminology in the social sciences—although many colloquial terms are used in both the natural and social sciences, but are imbued with technical meanings that can be confusing to students (Moje, 2010). For example, *market* is a complex economic term yet students are familiar with its more colloquial and common usage as a store where they can buy food; similarly, the word “genes” is a word with which most youth are familiar, but whose technical meaning may be elusive or simply misunderstood. The word *ecosystem*, however, has fewer everyday meanings and students can more readily identify it as scientific language (Moje, 2010), even if they are unsure of its definition.

These aspects of content area text can be challenging for students, and teaching students to recognize language as important to understanding can help illuminate the sources of difficulty. Fang and Schleppegrell (2010) posited that student writing can also be shaped and improved by calling the attention of students to language and in particular to the three types of meaning presentation described by Halliday: (a) ideational meaning, which is located in the content; (b) interpersonal meaning, which is developed through voice and intended audience; and (c) textual meaning, which comes through the structure of language as communication. Schleppegrell and Go (2007) argued that students need to be taught to attend to what a text is about, how it expresses judgment and evaluation, and how it is organized or structured.

With a specific focus on history learning, Coffin (2006) argued that students in general need explicit instruction in and access to “the written texts of mainstream education, for example, a persuasive essay, a laboratory report, or a critical review of an artwork or literary text” (p. 414). In addition, students need instruction—and teachers need training—to help them understand how “texts are linguistically structured and shaped and the way in which writers draw upon grammar and lexis . . . to create different communicative effects” (p. 414). To bolster these claims, Coffin collected samples of student writing in secondary history classes and engaged in a comprehensive linguistic analysis of patterns of causal relations and the structure of arguments. Based on her findings, Coffin structured professional development experiences for teachers in which they worked with linguists to identify key structures and features of model texts. Teachers used this framework to provide explicit instruction around language. Students began with exercises that explored processes like nominalization, transitioning from phrases such as *Europeans invaded* to *invasion* in the next sentence to carry the idea forward. They then worked to integrate these practices into their own writing by first engaging in the joint construction and public production of texts on the whole class level.

An understanding of the linguistic features and structures of content area texts and the reading processes involved is helpful for educators, curriculum developers, and textbook authors as well. However, attention to language is not enough in and of itself. A linguistic approach to disciplinary and content area reading is but one way to consider instruction and research in this area (Moje, 2007). Attention to cognition, social and cultural connections, and disciplinary thinking or epistemology is also important. Moreover, attention to reading process and language does not explicitly address questions about the knowledge that students need to make sense of disciplinary texts. Content area texts generally assume a certain amount of prior knowledge on the part of the reader and instruction needs to take into account the dimension of reader knowledge. When integrated with the development of necessary knowledge and with making connections to young people’s home and community experiences, attention to the language features of content area dialogue and texts, such as genre, register, grammar, and vocabulary, can help students develop deeper

comprehension and knowledge in their content area classrooms. Teacher education, both pre- and in-service, can also address these issues and raise teachers' awareness of the importance of attending to language in use in content area reading and instruction.

Reading and Intertextuality

DAVID BLOOME AND HUILI HONG

Intertextuality can be defined as the juxtaposition of two or more texts. The juxtaposition of texts is ubiquitous in everyday life, in scholarly discourse, and in and across the social institutions of a society. Kristeva is credited with originating the term *intertextualité* in the 1960s (see Kristeva, 1986). There are, however, numerous related terms (Orr, 2008, lists approximately 1,200 closely related terms), many of which predate the coining of *intertextualité*. Although discussions of intertextuality are “at least as old as recorded human society . . . [and] we can find theories of intertextuality wherever there has been discourse about texts” (Worton & Still, 1990, p. 2), Kristeva’s originating of the term can be viewed as part of a broader effort to transform how meaning in texts and language might be understood (Kristeva, 1980) by bringing Bakhtin’s concept of dialogism (Bakhtin, 1935/1981) into contemporary discussions in literary theory, linguistics, and social theory (see Orr, 2008). Kristeva defined *intertextualité* as “the transposition of one or more systems of signs into another, accompanied by a new articulation of the enunciative and denotative position” (Kristeva, 1980, p. 15). The concept of *intertextualité*, as formulated by Kristeva, challenges scientific positivism, monologism, and ahistorical understandings of text (Orr, 2008). Thus, despite diverse definitions of intertextuality and debates about the scope and usefulness of the term (see Worton & Still, 1990; Allen, 2000; Irwin, 2004), what is at issue in the term “intertextuality” is not the simple juxtaposition of texts per se, but the deconstruction and reconstruction of dominant theories of semiotics, linguistics, hermeneutics, language, reasoning, and related topics including reading, composition, literary theory, and how a text is defined.

There are differing definitions of intertextuality based on what counts as a juxtaposition, how juxtapositions are accomplished, and how a juxtaposition of texts might count in constituting meaning(s) and social consequence(s). With regard to the former, scholars have focused attention on how juxtapositions are accomplished (inherent to the text, by the text’s membership in a particular class or field, by the reader, through social interaction). With regard to how a juxtaposition might count, scholars have focused on how meaning is realized through a juxtaposition of texts themselves, how juxtaposed texts are related to discourse formations and cultural ideologies, and how juxtapositions of texts are taken up by, interpreted by, and used by people in meaningful ways including the (re)structuring of social relationships, social institutions, and social/cultural ideologies.

Within the last few decades, views and definitions of intertextuality have expanded by moving beyond consideration of literary texts to other cultural and artistic productions (Allen, 2000) and to the texts of everyday life including various modalities and media (e.g., Hanks, 2000; Meinhof & Smith, 2000). This expanded focus has been accompanied by a broadening of the theoretical foundations of intertextuality to include discussions of deixis, indexicality, memory, time and space (e.g., Hanks, 2000), power relations (e.g., Fairclough, 1992), and social interactions among interlocutors (e.g., Bloome & Egan-Robertson, 1993). The expanded focus has also been accompanied by interest in intertextuality in a broad range of disciplines and fields such as cognitive science (e.g., Goldman, 2004; Segev-Miller, 2007), semiotics (e.g., Lemke, 1995), anthropology (e.g., Briggs & Bauman, 2009; Hanks, 2000), history (e.g., Rouet, Britt, Mason, & Perfetti, 1996), education (e.g., Shuart-Faris &

Bloome, 2004). The underlying premises of such studies of intertextuality, to greater and lesser degrees, include three premises articulated by Boyardin (1990, p. 12):

The first is that the text is always made up of a mosaic of conscious and unconscious citation of earlier discourse. The second is that texts may be dialogical in nature—contesting their own assertions as an essential part of the structure of their discourse . . . The third is that there are cultural codes, again either conscious or unconscious, which both constrain and allow the production (not creation) of new texts within the culture; these codes may be identified with the ideology of the culture, which is made up of the assumptions that people in the culture automatically make about what may and may not be true and possible, about what is natural in nature and in history.

What counts as a juxtaposition, and how the juxtapositions of texts count, is contextualized by various discourse communities and the social, cultural, historical, political, and economic relationships among those communities.

What Counts as a Juxtaposition

One focus of scholarship on intertextuality has been on the features of text that explicitly reference other texts, including citations, references and bibliographies, reported speech, and explicit mention of other texts. Similar explicit features include text genres and book series that are by definition intertextual such as book reports, book reviews, and fiction sequels. Slightly less explicit are juxtapositions signaled by a distinctive writing style (e.g., children's books written in the rhyming style of Dr. Seuss).

Beyond the level of words, sentences, and writing style, scholars employing the concept of intertextuality have focused attention on the explicit and implicit relationship of one particular text with another (e.g., how Shakespeare's *King Lear* influenced Melville's *Moby Dick*; see Olson, 1947), how texts "influence" each other more generally (Clayton & Rothstein, 1991), and the role of a text in a sequence of texts (e.g., a diagnostic medical report leads to a pharmacy prescription; field notes lead to an ethnographic report; see Fairclough, 1992 on sequential intertextuality).

The juxtaposition of texts may also be a function of the reader and what "texts" the reader brings to the reading of a particular text (and how the reader brings those texts). A reader may read a target text with a memory of another text (spoken, written, visual, etc.) that she or he views as related. A reader may also bring to a target text personal experiences and knowledge that are useful for interpreting the target text. To characterize a reader's use of prior knowledge and experience as an intertextual process requires an assumption that prior knowledge and experience are also texts (see Volosinov, 1929/1973; Gee, 1985). Some formulations of the representation of meaning in memory by cognitive scientists also suggest that readers bring prior knowledge and experience to a reading as prior texts (e.g., Tulving, 1983). To the extent that reading with understanding requires the reader to bring to the target text some level of previous knowledge represented as text, all interactions between a reader and a text can be viewed as inherently intertextual.

The juxtaposition of texts may also be a function of the reading task and its interpersonal context. For example, in secondary-school history classes in the United States, students are often given a set of texts and asked to construct a historical representation based on that set of texts (simultaneous intertextuality; see Goldman & Bloome, 2005). Even when students are asked to read a single text, teachers may first prompt recall of related texts or frame the reading in terms of an upcoming test (itself a text) or composition assignment (successive intertextuality; see Goldman & Bloome, 2005).

The interpersonal context of the use of a text may also be implicated in the juxtaposition of texts. Although archetypal views of reading events envision a single reader and a single

text with a single authorized meaning, reading events often involve multiple people reading multiple texts, all interacting with each other (as might occur in a classroom where the students and the teacher are discussing comparisons between two stories they have read and the argumentative essay they are to compose). The illusion of the archetypal view and its contrast with the empirical reading event is highlighted in a study of elementary schoolchildren by Sterponi (2007). She documented how the students resisted the imposed one-reader-one-text-one-interpretation stance toward reading through clandestine interactions among themselves.

Every text can be viewed as inherently belonging to at least one class of texts and to at least one field of texts. A class of texts is similar in text type, genre, constitution, or modality. The field of texts can be viewed as the institutional domain of the use of a text. The institutional domain defines the social relationships contextualizing the use of the text. For example, *Where the Wild Things Are* (Sendak, 1988) belongs to the class of texts described as picture books, children's literature, fantasy, or dream stories. It belongs to the field of texts used in families and early childhood education, defined by and defining social relationships as parent-child and teacher-pupil respectively.

A text is inherently juxtaposed with all the other texts within its class and field, both individually and as a whole. As such, any text can be viewed as always indexing its particular class(es) and field(s). A text that is taken from one class or field and placed in another is recontextualized. Thus, the film version of *Where the Wild Things Are*, as well as having an intertextual relationship to the book and thus also to that book's class and field membership, is related to the class of texts that might be labeled as movies for children; and while its fields may still include the social institution of family, the film does not belong to the field of bedtime story reading.

The recontextualization of a text may create a new set of meaning potentials such as occurs when a text from one discipline is imported into another. Interdisciplinarity requires the juxtaposing of texts in a manner that creates a system of new meaning potentials not available in either of the previous disciplines' classes or fields (as opposed to multidisciplinary, which can be defined as involving the parallel play of texts from varying disciplines and the potential for new meaning, but not the creation of a new system of meaning potentials). For example, the incorporation of chaos theory, a set of texts from mathematics and physics, into cultural anthropology (see Agar, 2004) creates new approaches to cultural analysis and definitions of cultural phenomena and processes.

What unifies the varying definitions of intertextuality above is that intertextuality is a primary characteristic of text and of reading; not an add-on or an accoutrement, but rather the essential nature of text and reading themselves. As Hanks (2000, p. 267) notes, "The important point is to realize that intertextuality displaces the object of study from individual texts to transtextual relations." As such, the term "text" as an integral, autonomous phenomenon is a non sequitur and might better be labeled an "intertext." The meaning potential of each text lies not in the text alone but in the relationship(s) of that text to the system of texts with which it might be juxtaposed within a field and a discourse community (see Porter, 1986).

Part of what is at issue is the degree to which the relationship of texts to each other is viewed as historical. Volosinov (1929/1973) argues that every word has a historical relationship to how it was used before and how it will be used in the future, each use reflecting and refracting its history. Whenever a person encounters or creates a text, the text does not come new, but with a history that contextualizes how its meaning. In this sense, any word, utterance, or text is always dialogic and always juxtaposed with what came before and what will come later. From this perspective, the contrast between dialogism and monologism is not about the inherent intertextuality of a text but about the stance taken toward a text: historical, dialogic, and heteroglossic or stable (ahistorical), monologic, and autonomous.

Bloome and Egan-Robertson (1993) take a slightly different approach to the inherent intertextuality of a text. Grounded in interactional sociolinguistics (see Gumperz, 1986), they argue that the juxtaposition of a text lies not in its nature *per se*, but in the social interaction of people using the text. Intertextuality is socially constructed and the set of texts that can appropriately be juxtaposed is also socially constructed. Intertextuality, from this perspective, consists of a series of situated social practices involving the use of texts that are adopted, adapted, contested, and transformed, as people interact with each other to accomplish the doings of their everyday lives.

Whether intertextuality is located in the text itself, in its class(es) and field(s), in the reader, in the task, in historical processes, or in social interaction, what counts as a juxtaposition of texts requires consideration of explicit and implicit intertextual references and signs, relationships among texts at multiple levels, the constraining and enabling role of discourse communities, and evolving ideological systems of texts. However, the significance of intertextuality is not in the mechanisms of juxtaposition *per se*, but in the ontological stance accompanying the juxtapositions.

How Juxtapositions of Texts Count

Rather than view a text as having a meaning warranted by the content and structure of its propositions (its text base), the concept of intertextuality frames meaning as deriving from the interplay of a text with other texts. The set of texts that might be juxtaposed and the ways meaning might be derived from their juxtaposition is constrained by the discourse community within which the text is being used and its intertextual practices. The set of intertextual practices of historians differs from that of physicists, bankers, lawyers, and automobile mechanics. Intertextual practices also vary across the social institutions of people's everyday lives such as family, recreational sports, the workplace, church, and so on. Intertextual practices within a discourse community are not fixed but are constantly being adapted and transformed; what texts are juxtaposed, how, by whom, when, and where, are constantly evolving. Thus, as Frow (1990, p. 46) quoting Culler (1981, p. 117) points out,

'There are no moments of authority and points of origin except those which are retrospectively designated origins and which, therefore, can be shown to derive from the series for which they are constituted as origin.' The prehistory of the text is not a given but is relative to an interpretive grid.

From a cognitive perspective, Goldman (2004) describes three intertextual models: the integration of multiple sources, an assimilative mode in which one text is "'swallowed up' by the other" (p. 328), and an "encapsulated" model in which the various texts remain relatively unaffected by the others, the inconsistencies across the texts unacknowledged (this "encapsulated" model is no less an intertextual relationship than the others, the meaningfulness lying in the separation; see Segev-Miller, 2007, for a similar description of intertextual models from a cognitive perspective). As Goldman notes, "the different ways that information across texts is related has implications for the construction of coherent mental representations" (2004, p. 344). In educational research, researchers have examined, among other topics, students' intertextual practices in written composition (e.g., Beach & Anson, 1992; Segev-Miller, 2007), how children and young people use intertextuality to build scientific understandings (e.g., Pappas, Varelas, Barry, & Rife, 2004), how they acquire historical knowledge (e.g., Perfetti, Britt, & Georgi, 1995), how they build literary understandings (e.g., Cairney, 1990), how students read for information (e.g., Hartman, 1992), and how they learn from digital, hypertext sources (e.g., Voithofer, 2006).

The heteroglossic nature of comprehension and interpretation characterizes not only the object of interpretation, but also the processes of text production and consumption. That is, the concept of intertextuality challenges models of language, semiotics, and communication in which an author or speaker encodes a meaning or intent into a text that is decoded by a reader or listener. It is replaced by a more diffuse, diverse, contested, and historical set of processes in which traditional conceptions of author, reader, and interpretive process are problematized and fictionalized. As Hanks (2000, p. 13) writes,

What we call a work is actually a history of concretizations, then the meaning of any historical document is the trajectory of its reception. The first step in this trajectory is the making of the document itself, a production typically involving witnesses, scribes, and other institutional supports.

It is not just that meaning is no longer located solely in a text; but rather that the production and consumption of texts is inherently a heteroglossic, dialogic, and discursive construction taking place in spaces mutually defining and defined by these intertextual processes (Hanks, 2000). For example, the creation and production of the book *Where the Wild Things Are* involved an author, an illustrator, copy editors, a publishing company, a literary agent, marketing representatives, distributors, copyright and government officials, bookstore employees, consumers (e.g., parents, educators) who purchased the book, administrative assistants, printers, librarians, tax accountants and others, and all of the texts they created as they worked together and interacted with various audiences, constituencies, and institutions. Collectively, they locate the book within particular fields and spaces (including social institutions such as families and schools, Western English-speaking geographies, and socioeconomic classes and cultures that enact bedtime story reading, etc.). The "authoring" (production) of the book not only reflects a class and field of texts, but contributes to a representation of childhood both by the social practices promoted (which themselves become textualized) and by the nature of the story rendered in the words and pictures of the book as it plays against other stories and texts.

The context of consumption is also a set of intertextual practices involving multiple people, texts, and agendas played out against a differing social and cultural system of (inter)texts and (inter)textual practices. Within the context of consumption, the meaning constructed from the book involves more than an individualistic, mental situation-model associated with the story rendered (itself derivative of multiple texts juxtaposed with the target text). It also involves a set of social relationships (parent-child), social spaces (home), cultural practices (bedtime story reading), social institutions (family and the relationship of family to school), and a cultural ideology associated with an economic class (a middle-class culture of child rearing), all of which becomes textualized as these experiences are talked about, remembered, reflected upon, used as a basis for similar future activities, separated in time and space from other activities, and otherwise made meaningful.

Some scholars include interdiscursivity as a form or extension of intertextuality (e.g., Fairclough, 1992). The texts of one discourse community are juxtaposed with those of another. Interdiscursivity can occur at the level of words and sentences, at the level of genres and writing styles, or other levels. For example, the texts of international economic competition might be juxtaposed with the texts of reading education (as occurs in Anderson, Hiebert, Scott, & Wilkinson, 1985). The consequences of such interdiscursivity may be to redefine one discourse community in terms of the other (what Althusser, 1971, called interpellation); thus, reading education becomes a matter of economic policy. Alternatively, interdiscursivity can open up new forms of expression and new meaning potentials. For example, Tupac Shakur's hip-hop song "Changes," with its sampling of Bruce Hornsby's melodic song "The Way It Is," helped lay the foundations for a new expression of social and

cultural critique. Such interdiscursivity reflects past texts but refracts them in the creation of new meaning potentials and in creating potential for new discourse communities.

Several scholars have argued that what is at stake with the concept of intertextuality is not simply the meaning of a text, but rather how it indexes a crisis with dominant theories of language, semiosis, and knowledge.

By proposing the connectedness of texts it puts the category of text itself into crisis; by pointing to the semantic connectedness of texts it focuses on the processes of semiosis and points away from the form-based starting point of most linguistic theories. By making text prior—text as produced out of elements of prior texts—it puts into crisis the structuralist/generativist notions of the generation of linguistic form. (Kress, 2000, p. 153)

As the set of texts (prior texts in Kress's terms) and intertextual practices within a discourse community evolve and change, as the boundaries of a text are recognized as diffuse rather than fixed, the stability of meaning and what counts as knowledge and as knowing is placed at risk. The concept of intertextuality calls for "dialogue," an interplay of texts, voices, practices, cultural systems, and ideologies, which may be responsive to each other but are not necessarily predictable or mimetic, but instead creative, transformative, and potentially carnivalesque (see Bakhtin, 1935/1981).

Reading and Language for Specific Purposes

WILLIAM GRABE AND FREDRICKA L. STOLLER

The uses and development of reading skills in Language for Specific Purposes (LSP) contexts have been, oddly enough, rarely discussed in recent years, even though LSP students typically study a second or foreign language for academic or professional purposes that entails substantial reading. The focus of attention in the LSP literature has rather been on other topics, with reading and reading-skills development only mentioned peripherally, if at all. For example, many LSP publications explore the role of input in instruction or reading-writing relationships; a number of needs analysis studies simply identify reading as an important skill for advanced LSP students; a few articles note the importance of reading, but then explore teaching technical or topic-specific vocabulary or complex sentence structures; and many articles discuss the general task of writing from sources. In most cases, reading abilities are simply assumed to be important, even though many LSP students begin their studies with poorly developed reading skills. Within this range of publications, almost no discussion exists of how to develop reading curricula or how to teach reading skills that would be useful for LSP students in undergraduate, graduate, or specialized professional-training contexts. In this brief entry, observations on the paucity of discussion about LSP reading and reading-skills development are addressed further. The entry also outlines ways in which this lacuna can be addressed in LSP contexts. An emphasis is placed on tertiary-level English for Specific Purposes (ESP) and English for Academic Purposes (EAP), the latter a subbranch of ESP, because of their predominance worldwide (Gnutzmann, 2009).

Waning Documentation About LSP Reading

The absence of concentrated attention to reading in LSP is widespread. A review of teacher-training volumes providing overviews of ESP research and instruction from the last decade reveals practically no consideration of reading-skills development or specific uses of texts in instructional tasks. These volumes include some discussion of the integration of content and language objectives, but, unlike explorations of writing instruction, little discussion is provided on how reading skills might be developed for ESP students. Similarly, a review of the last five years of journal articles in *English for Specific Purposes*, *Journal of English for Academic Purposes*, *TESOL Quarterly*, and even *Reading in a Foreign Language* (RFL) reveals almost nothing concerning the reading-skills development needs of LSP students, though limited research on reading motivation and strategies in ESP contexts is reported. One RFL article reports on the serious English reading difficulties experienced by Norwegian university students, due to impoverished vocabulary, slow reading, and overall poor language proficiency (Hellekjær, 2009). Overall, this gap in reports on LSP reading research and instruction is surprising given that so many LSP contexts around the world, and especially EAP contexts, recognize reading as a crucial ability that students need to develop for success in their studies or professions. This dearth of attention to reading is also somewhat striking because early discussions of ESP, especially English for Science and Technology

The Encyclopedia of Applied Linguistics, Edited by Carol A. Chapelle.

DOI: 10.1002/9781405198431.wbeal0997

(EST), were heavily devoted to the development of reading skills (Hudson, 1991; Flowerdew & Peacock, 2001; Celani, 2008).

In several countries, English as a foreign language (EFL) serves as the medium of instruction across or in a number of academic departments in key universities. In these contexts, non-native English students are expected to read materials in English that are relevant to their studies and professional training even though a high percentage of students are not skilled English readers. In many other EFL university settings, students pursuing degrees in science, technology, engineering, and math are expected to take English reading courses—in foundation programs or English language preparatory programs—to develop English reading skills. These programs are meant to bring students' proficiency level up to the basic minimum required for study in their chosen fields. Typically, these courses are less than fully successful for their stated goals because (a) students begin as false beginners in EFL reading, and (b) so few hours of instruction are provided that students do not have the time to become reasonably skilled readers, even when just concentrating on disciplinary specializations (see Dharmapriya, 1988; Anwar, 1994; Cobb & Horst, 2001; Ward, 2009).

In the years 1980–2000, the role of reading in ESP settings was treated in much greater depth. In the mid 1980s, Hutchinson and Waters (1987) promoted a strategy-based approach to ESP reading. Hudson (1991; see also Lynch & Hudson, 1991) reported on a detailed approach to a content-based EST reading curriculum in Mexico that was developed as part of a five-year research project. This work may be the single best earlier discussion of reading instruction in an advanced ESP context, and perhaps the only one to demonstrate empirically that their approach led to significant gains among students in the program. A Brazilian ESP project, that began in 1978 and continues to this day, places importance on the role of reading-skills development for ESP students and in ESP teacher training (Holmes & Celani, 2006; Celani, 2008; see also *ESpecialist Journal* for other relevant articles). And finally, Dudley-Evans and St. John (1998), in their often mentioned ESP volume, addressed the development of reading abilities from disciplinary texts.

The more recent shift away from reading, or a shift to assuming acceptable reading abilities among LSP students, is evident in the much greater current emphasis placed on writing abilities, genre awareness, discourse analysis, corpus studies, and students' socio-cultural needs in LSP contexts. Nonetheless, a number of key publications since 2000 describe the role of reading in LSP and report interesting research. Carson (e.g., 2001) describes advanced EAP reading and writing instruction from a task-based perspective that is still important today. Hirvela (2004) addresses reading–writing relationships and includes discussions of the importance of reading skills in EAP contexts, both as an outgrowth *from* writing tasks and as a key resource *for* writing tasks. Parkinson, Jackson, Kirkwood, and Padaychee (2007) provide a useful discussion of a curriculum project in South Africa. In this project, a 26-week curriculum draws upon sets of science texts for EAP content and builds eight three- to four-week thematic units designed to develop both reading and writing skills for foundation-level science students. At very advanced levels of disciplinary literacy training, Robinson, Stoller, Costanza-Robinson, and Jones (2008) promote a read-analyze-write approach to chemistry-specific literacy development that situates reading at the beginning of the process.

Despite these few recent explorations of LSP reading, the gap that exists in LSP/EAP research and curriculum vis-à-vis reading is surprising given the continuing strong emphasis on reading-skills development as a common goal of many tertiary-level EAP and ESP curricula, especially in EFL contexts. In the remainder of this entry, we introduce the reading skills needed by LSP students and offer suggestions for curriculum development and reading instruction.

Reading Skills and LSP Curricula

Most LSP needs analyses that have been reported validate the strong importance of reading skills in LSP contexts. Even though LSP and EAP contexts can vary enormously, LSP and EAP instruction at the tertiary level in many countries share some features. For example, students are generally assumed to have at least a low-intermediate knowledge of English vocabulary and grammar (however that might be defined), and they may have had some reading-skills practice, but little extensive reading in English (Gnutzmann, 2009). In LSP contexts, students are usually not English majors and reading-skills development has been identified as a major focal point for typical two-year English curricula (often one and a half to two hours per week, for a range of 105–40 hours of total instruction over two years). Students are expected to become fairly competent readers at the end of four semesters, at least within the narrow scope of their majors. Although not explored much in the LSP literature, publications on reading-skills development (e.g., Grabe, 2009) suggest that if students such as these are to have any degree of success with reading disciplinary materials in English, they need to

- develop a large recognition vocabulary (with an emphasis on disciplinary terminology);
- comprehend main ideas in (often complex and difficult) texts;
- recognize how texts are organized and how parts relate to each other;
- read strategically to achieve task purposes and maintain comprehension with longer texts;
- use text information to produce summaries, write syntheses, and evaluate information critically;
- use readings in English as input for learning disciplinary content;
- read extended discipline-specific texts fluently.

In truth, it is not a feasible pedagogical goal to develop all of these abilities in relatively limited instructional contact hours. This limitation in instructional time explains why LSP students commonly do not meet institutional expectations in terms of becoming skilled independent readers of disciplinary texts in English. In settings where students begin with a good foundation in English reading skills, considerable progress can be made, and instructional gains can be achieved.

A number of curricular principles for LSP courses that aim to help students improve their reading abilities are likely to be useful (Grabe, 2009). As far as possible, LSP reading curricula should be structured around these recommendations:

1. Use reading resources that are relevant, interesting, varied, and accessible.
2. Provide some degree of student choice.
3. Introduce and practice reading skills by first drawing on course texts for instructional examples.
4. Structure lessons around a prereading, during reading, and postreading framework.
5. Build connections between instructional texts and student background knowledge.
6. Provide opportunities for students to experience comprehension success.
7. Build expectations that reading occurs in every lesson.
8. Plan instruction that supports a number of developmental goals (see below).

Many of these general curricular recommendations (1–8) are straightforward but are often absent in LSP/EAP reading instruction. To the extent that these curricular guidelines can become regular components of reading instruction, more students will achieve some success in LSP/EAP instructional contexts. A more complete snapshot of what should occur

in an LSP/EAP reading course is achieved by expanding upon the developmental goals suggested in the eighth recommendation (above).

Reading Development Goals

To prepare LSP students for the demands of reading for specific purposes in their chosen fields of study, at least seven developmental goals should be supported through deliberate instruction (Grabe, 2009). From a teacher's perspective, instruction needs to

- build a relatively large recognition vocabulary (emphasizing academic and disciplinary vocabulary),
- use texts relevant to students' LSP needs and goals,
- provide practice with comprehension skills,
- build awareness of text structure,
- develop the strategic reader,
- promote reading fluency,
- motivate students to read,
- assess students' progress and development.

Each of these developmental goals requires ongoing attention and practice, and some deliberate efforts on the part of the LSP instructor, as discussed in the remainder of this section.

It is not realistic to expect LSP/EAP students who commonly have only one and a half to two hours of English instruction per week in many EFL settings to build a large reading vocabulary. Yet, with instructor encouragement, LSP students can work toward building a reasonably large recognition vocabulary centered on disciplinary and subtechnical academic words and phrases. Students should be exposed to many words by (a) identifying words in texts that they do not understand and finding out what these words mean, (b) studying word meaning lists and testing themselves on these words, (c) working with flash cards to practice word learning regularly outside of class, (d) learning to infer word meanings reasonably efficiently while reading, (e) collecting words that they find interesting in a word journal, (f) learning word family members and learning common derivational morphology for word building, and (g) using dictionary resources efficiently. These word learning suggestions would differ considerably in a teaching context with many more instructional contact hours, but instructional time limitations oblige students to take on more responsibility for word learning and require multiple brief encounters with words.

Texts assigned in LSP/EAP courses should be content-based, centering on relevant thematic materials, though they should be matched fairly closely to students' reading abilities. This expectation may lead to more texts being selected from content-area textbooks than from textbooks written specifically for language learners. A balanced text-selection approach, that combines simpler and more general nonspecialist texts with a smaller set of research-oriented academic texts, may be the most effective compromise.

LSP students need to focus most centrally on comprehending assigned texts. Building main-idea comprehension involves a combination of identifying main idea statements in the texts, sorting through complex lexicogrammatical information in key sentences (e.g., extended nominalizations, complex embedded clause structures), using comprehension strategies appropriately, and becoming aware of how discourse structure helps organize information in texts. Teaching comprehension strategies to students should not be carried out as a strategy-per-week, but rather as a consistent process of using strategies in every class to determine how best to understand a text. Both strategy instruction and discourse

structure awareness should be exemplified with the primary texts being used for instruction, not with separate texts brought in solely for those purposes.

As far as possible, students should be encouraged to read longer texts and for extended periods of time. In some cases, longer texts can be read faster and at lower comprehension levels if the assigned task is not too demanding. In this way, students practice working with longer texts and achieve some level of success. If resources are available and if the institution wants students to gain some level of reading fluency, then an extensive reading component should be integrated into the curriculum (Day & Bamford, 2002). Ultimately, if students are expected to become fairly skilled readers in English, they will need to read extensively. There is no short cut to becoming a good reader. Students only become readers by reading regularly (Grabe, 2009).

A concern sometimes expressed about LSP reading courses is that students are not motivated to work on their reading-skills development or read beyond minimal requirements. At one level, motivation depends on the institutional culture and levels of expectations; in cases where there are low institutional expectations and goals, it is difficult to address student motivation directly. In these settings, teachers need to locate sources of student interest and engagement. Teachers can also incorporate reading tasks into their instruction that (a) allow students to experience success on a regular basis, (b) lead to stimulating extended projects, (c) give students some degree of choice in task options or texts to be read, and (d) promote group support and collaboration. In situations in which institutional expectations are higher, a wide range of specific motivational objectives can be incorporated into classroom instruction to build student motivation and engagement (see Grabe, 2009; Guthrie, Wigfield, & Perencevich, 2004).

Assessment of reading improvement should be a regular feature of LSP reading instruction. Typically, reading achievement tests are used to determine student learning and to identify students' needs for continued reading-skills practice. Often, postreading comprehension questions and related tasks are used to gauge student success. While assessment of reading improvement is an expected part of most reading curricula, it is also important to recognize the value of "assessment *for* reading," an approach to helping students learn essential reading skills without the burden of grades for every task type. In fact, "assessment *for* learning," rather than "assessment *of* learning," is more likely to help students improve their reading skills over a longer curriculum time frame (see Davison & Leung, 2009; Grabe, 2009).

Limitations and Realistic Goal Setting

Reading instruction in LSP contexts varies widely. Certainly, LSP/EAP reading instruction for graduate students in more specialized contexts necessitates well-articulated instructional goals and higher expectations of students; students in such settings require higher motivation to succeed and greater engagement with realistic disciplinary material. In settings with well-articulated goals, such as reading-to-write a thesis, ESP/EAP instruction can guide students in reading purposefully and effectively so that they can use information from key sources in their written work.

The number of graduate students in specialized LSP contexts is fewer than the number of undergraduate students with LSP needs, especially in EFL settings. The undergraduate with LSP reading needs—enrolled in, for example, English foundation or preparatory programs—creates many challenges for teachers and students alike. In sorting through the challenges associated with reading-skills development, it is clear that true beginning students cannot learn to become reasonable readers of English in two years of reading instruction with minimal contact hours and low motivation to succeed. Often text materials

selected for such LSP courses are too difficult for students, selected because it is assumed that students want to read authentic content-area texts and will be supported by their background knowledge and common technical terminology. No empirical research that we know of supports such assumptions. Perhaps the most formidable challenge facing LSP teachers is the minimal number of hours commonly dedicated to their LSP courses, sometimes with unrealistically high expectations or, conversely, sometimes with few expectations. Either setting makes real reading gains difficult to achieve. Finally, there is often a lack of awareness on the parts of both teachers and administrators that students only become good readers if they read regularly and read a lot. If students are to become reasonably good readers in English, they need to read beyond the materials covered in class and they need to read on their own. Unfortunately, this is not a common outcome of many LSP reading curricula.

Reading–Writing Connection

JEROME C. HARSTE

I have often said to teachers, “If your reading program is having problems, your writing program probably has problems too. And vice versa, if your writing program is problematic, your reading program is more than likely problematic too.” While some people may think these statements are speculative at best, what follows is an analysis of what we know about the reading–writing connection and why these statements are more fact than speculation.

Parallels between reading and writing exist at the graphophonic (letter–sound), structural (syntactic), semantic, and pragmatic levels of language. Parallels also exist between all of the expression of language, not only between reading and writing but also between reading and writing and speaking and listening. Carolyn Burke (see Harste, Woodward, & Burke, 1984) has referred to these parallels as a “linguistic data pool,” by which she means that experiences in any expression of language become a resource to be used when engaging in another expression of language. What you learn from speaking (what to call things, how to talk about a topic, how language does the work it does) becomes a resource when you engage in another expression of language, be it reading, writing, listening, or speaking. Burke’s model suggests a synergy between reading and writing. It is not just that reading and writing are correlated but rather that in juxtaposition they are generative, allowing language users to make leaps in terms of their growth and development as language learners.

Although these understandings may not have represented new ways to think about teaching children to read and write (Sprague Mitchell, 1950; Stauffer, Burrows, Coleman, & Swain, 1960; Jacobs, 1965; Hunt, 1980), they did suggest new avenues for research. In the 1960s researchers interested in the reading–writing connection studied it using correlation. Specifically they studied the relationship between spelling and phonetic knowledge. The correlations were always low, around .20, which when doubled explained only 4% of the variability found between spelling scores and reading scores. Hanna, Hanna, Hodges, and Rudorf (1966) fed a computer all of the known phoneme–grapheme correspondence rules of English (17,310 words) and then asked the computer to spell as many words as it could correctly. The relationship between phonetic rules and the correct spelling of words was much higher than anyone expected. While a quarter of the words not spelled conventionally were the highest-frequency words in the English language, the computer was able to spell correctly almost three-fourths of the words it was fed!

While surface-level studies of language have helped advance our understanding of the reading–writing connection, breakthroughs in our understanding of how we learn language were needed. In the 1960s teachers were told not to teach reading and writing together to young children. The assumption was that teaching both subjects together was too much information for the young child to take on. The advice given was that writing should not be introduced until after the child had learned to read, by which educators at that time meant learned the fundamentals of sounding out words and had a sufficient sight vocabulary to recognize function words “with automaticity” (Laberge & Samuels, 1974, p. 294). By “automaticity” Laberge and Samuels meant that sounding out had to be automatic so that attention could be focused on meaning. They saw reading as the mind having to

do two things at once. Given new insights into language and learning this advice is questionable, with some theorists arguing (Goodman, 1996) that separating the systems of language makes the learning of both reading and writing harder than when they are taught in conjunction with one another.

Graphophonic Parallels

I am not going to argue against the direct teaching of phonics. However, I will argue that encouraging writing, and hence invented spelling, incorporates the best of what we know in terms of supporting literacy learning. P. David Pearson (2002) explains:

At the most rudimentary level, when kids are encouraged to write—even at the very early age, pre-kindergarten and kindergarten—and they're encouraged to spell words as they sound them, two things happen. The first is that they develop phonemic awareness in precisely the way that the advocates of direct phonemic instruction intend for it to be learned and tested. But with writing, they do it, I would argue, in a much more incidental, less laborious, and more natural way. And it's acquired in the service of some other functional task, i.e., trying to communicate something with someone. (p. 1)

Our own research on what preschool children know about reading and writing prior to going to school (Harste et al., 1984) shows that all English-speaking children by age 6 come to school with some grapheme–phoneme knowledge. This was even true for children from inner-city settings and from areas where not much environmental print is found (such as on the Navajo Reservation). We also found that children as young as 3 years old could read certain items of environmental print, including “Stop” on a stop sign, “McDonald’s” on a McDonald’s cup, and “Milk” on a Kroger’s milk carton. While they were clearly using the context to make sense of what we asked them to read, it is important to note that not one child said “Wendy’s” or “Burger King” when shown a McDonald’s cup. Their responses were far more predictable based on the graphemes that were shown them.

The same was true with the children’s writing. While what they wrote was far from conventional, there was, nonetheless, a higher percentage of letters that corresponded to the message they said they were writing than one would predict if their production of letters were random. Children began by writing consonant letters but often place-held the vowels using a single letter. Alison, age 5, for example, used “o” over and over again and did so with surprising accuracy as to where vowels would be found in words (Harste et al., 1984, p. 54). The very fact that the children were writing letters instead of other shapes when asked to write verifies a very early reading–writing connection.

Even before children were writing letters in a conventional manner, we found that children whose name started with a curved letter (Shannon, Chris, Jerry) tended to produce circle-like shapes when asked to write whereas children with names that began with straight-line letters (Heather, Kezia, Ella) used more of a jagged up-and-down stroke to place-hold their writing. This was true in 93% of 3-year-old writing samples we studied. Often when children begin to form letters, it is the letters in their name that they repeat to place-hold their message (Clay, 2001). Our conclusion was that the child’s name constituted the child’s first “linguistic laboratory.” Megan, one of the children we were working with, when shown a McDonald’s cup, remarked, “Hey, that is the same letter as in my name!” The written language learning process begins to take on conventional forms with this kind of recognition, that the “m” in Mary and the “m” in McDonald’s make the

Figure 1 Sarah's mother's-day card © Jerome C. Harste

same sound. Our study, plus other studies of young children (Goodman, 1980; Baghban, 1984; Teale & Sulzby, 1986; Dyson, 1993; Martens, 1996), show that children at a very early age are attending carefully to print. While these studies focused on children in English-speaking communities, Emilio Ferreiro (1983) found the same could be said of South American children becoming literate in Spanish.

Equally surprising, we found that there was no order in language itself to the way it was learned. Children attended to what interested them based on their own experiences in language, learning, and life. One of my favorite writing samples is a mother's-day card which Sarah, age 5, created (Figure 1) (see Harste et al., 1984). When asked to read what she had written, Sarah read: "Once upon a time there was a loveable bunny who picked a rose for his mommy."

It is important to note that Sarah wrote "Once upon a time" as a single conceptual unit. While this is not a convention we use in English, Sarah is right in a very important sense. "Once upon a time" signals to the reader that this is fiction and hence the need to activate a different schema than one would if the text were nonfiction. Notice also that the majority of Sarah's text is written in word units and, although not conventionally spelled, most English-language users can read her text when asked to do so. In one instance Sarah writes using syllables as her graphic frame ("loveable" as "love a bal"), a move she probably made because of knowing how to spell the word "love." Sarah makes her "s"s like "z"s and does this consistently in words that end with the z-sound ("was" and "roses"). What is evident in this writing sample is that Sarah is testing multiple hypotheses about letter-sound correspondence. Her knowledge of graphophonics, already at 5 years of age, is extensive.

Charles Read (1975) was interested in children's phonological knowledge. He found that even misspellings such as writing "j-r-e-s" for "dress" can be explained by studying the point of articulation where letters are made in the mouth. "J" and "d" in this instance are both made at the same point of articulation. While not all children have as well-developed a sense of letter-sound correspondence as Sarah, by the time they enter first grade we found that all children have enough letter-sound knowledge to begin to build instruction from that base. Teachers of young children rarely, if ever, need to start from scratch when working on grapheme-phoneme correspondence.

Structural Parallels

Children with severe reading problems often have abandoned syntax as a significant cuing system. Often the only way to support them in learning to read is to re-establish the link between the syntax of oral language and the syntax of written language. Roach Van Allen (1976) understood this and made it one of the key features of his language experience approach to reading. Children were taught that what they could say could be written and read. Teachers using this approach begin by having children dictate stories or important events in their lives, which then become the texts they use when learning to read.

Most children, even most children with reading problems, never totally abandon syntax as a cuing system. Kenneth Goodman and Carolyn Burke (1973) found that the miscues of all readers—even young children—are substitutions of the same grammatical class. As is evident in Sarah's mother's-day card, Sarah has a well-developed sense of syntax or the flow of language. Like many beginning readers and writers she writes one idea per page, using the page itself, rather than a punctuation mark, as a vehicle to place-hold a sentence or complete thought.

Spacing, of course, is an issue. Figure 2 (Watson, 2007) is a message Eric taped on his classroom door. When asked to read his message, he said: "We are having reading. Don't come in. Thank you." He, like many beginning readers and writers, labored at sounding out the words. The result, in his case, was place-holding some words with only a few letters ("ha" for "having" and "ng" for "reading"). Other children who labor at sounding out words end up with a string of letters, thus elongating the word due to the oral repetition of the word during the writing process (like "skoohkooool" for "school"). Although not clearly shown in Figure 2, Eric uses red blots (which he said was "blood") to make sure readers understood he meant business. His "thank you" at the end suggests that he understands larger structural issues such as politeness and how it typically operates in school settings.

As is also evident in Figure 2, once children move to writing continuous text, other issues, like punctuation, come into play. It is not uncommon for children to throw periods all over their text once they realize that a period ends a sentence. Like other reading discoveries that end up in their writing, once something becomes known it is often overused and abused before it takes on conventional form.

Yetta Goodman (Goodman, 1979) received a letter from Bill, an elementary student in a school she had visited. Bill had developed a new exclamation mark which he called "the sadlamation mark." Here is what he had to say: "Dear Yetta Goodman, I've invented a new punctuation mark. A mark for something sad. It is used in a sentence like this. I had a dog, it died. It does look funny but it will get better looking soon, just like all of the others." (See Figure 3 for how to make Bill's "sadlamation mark.") Bill's letter documents one child's attempt to work out syntactic markings, and like Sarah, Bill goes beyond the

Figure 3 Sadlamation mark (Goodman, 1979) © 1979 by the National Council of Teachers of English. Reprinted with permission

conventions the English-speaking community have elected to use in transcribing its language into a written form (in Bill's case he invents a new punctuation; in Sarah's case she draws a distinction between when "s" is written "s" and when it should be written as a "z").

Semantic Parallels

One of the real benefits of writing is that thoughts become visible and hence revisable. Peggy Atwell (1981) says "The very first editor that a writer encounters is him- or herself" (p. 101). In writing, the hand often lags behind the mind, or the ideas being generated. That is why first drafts often contain syntactic errors or even misspellings of known word usages, like writing "there" for "their." This mind-hand gap is as prevalent in experienced writers as it is in children new to writing.

In the cloze procedure (Bormuth, 1970) every *n*th word in a text is deleted and readers or writers are asked to put in words that grammatically and semantically fit, using their knowledge of language and the world. Though sometimes frustrating for readers, as an instructional technique, it is surprising how many grammatically and semantically acceptable sentences are generated by children of all ages. Bormuth found from 38% to 70% accuracy. Shanahan, Kamil, and Tobin (1982), however, found that when the sentences in a story were randomized, participants did as well as when the sentences in the story were presented in their original order. These authors' finding suggests that, whatever cloze measures, it is not allowing readers to use larger semantic and syntactic structures that operate in connected discourse to make predictions and refine hypotheses.

Kenneth Goodman (1968, 1996) found that one's knowledge of the world is an important cuing system in reading, allowing readers constantly to predict and confirm their meaning making during reading. One of the strategies developed by Goodman and Burke (1980) was synonym substitution, in which readers were asked to replace underlined words in a text with synonyms as they were reading. Schema theorists (Anderson & Pearson, 1984) built on this insight and the importance of activating background knowledge as a key to successful reading. Writers, too, have been found to be most successful when they write about things they know (Britton, Burgess, Martin, McLeod, & Rosen, 1975; Graves, 1983). It should be said, however, that Barbara Kamler (2001) argues that to create critically literate individuals for the 21st century, we need to help readers and writers unpack the

personal in terms of the social constraints that are operating on the meanings they make and the stories they write.

Pragmatic Parallels

Pragmatics has been defined as the rules of language use operating in a context of situation (Halliday, 1975). To go back to a language sample already introduced in this text, one cannot help but hope Sarah (see Figure 1) gets a job with Hallmark when she grows up, as she already understands the genre of mother's-day cards. Sarah's example clearly illustrates that pragmatics is not something that is added on to language when everything else is in place, but rather is part and parcel of the language-learning process from the beginning.

The language of story is different from the language of newspaper and different again from the language of the Bible or the everyday use of language. Linguists would say that each genre has a different register or set of rules that operate. All language varies by context of situation. Hansen argues (1985) that writing for authentic purposes is very different than writing for the teacher. This is probably most easily illustrated with an oral language sample. Edwards and Westgate (1987) found that school talk is very different than talk outside of the classroom. The example they give is that Speaker A asks, "What time is it?" Speaker B answers, "3 o'clock." Speaker A responds, "Very good." This example of language use they say only happens in school where Speaker A has evaluated the quality of the response Speaker B has given. In the outside world if this event had occurred, one most likely would get a "Thank you" as a follow-up response.

We (Harste et al., 1984) found that experience is a bigger factor than age or stage in written language learning. The more experience children have with language in a variety of settings, the more readily they are able to produce successful texts in both reading and writing. Our advice was that if you want your children to sound and write like a lawyer, let them hang out with lawyers. By 6 years of age children's stories sounded and looked like stories, their personal letters sounded and looked like personal letters, and their notes sounded and looked like notes.

Because of prior experience, language users can predict the kinds of texts that are likely to be found in that particular context. One of the problems with the way reading is taught in schools is that the predictability between text and context is broken; teachers can pull out anything at any time to have children read. While this is part of the pragmatics of reading instruction, it does not allow readers to activate the pragmatic schema they may have for a particular genre, or even the background knowledge they may have about a particular topic. Normally, readers read things they have selected and writers write things they know about. In operation in the real world, syntax, semantics, and pragmatics are familiar given prior experience and operate as a framing device. As mentioned earlier, Kenneth Goodman (1996) argues that we often make reading and writing difficult by teaching the systems of language in isolation, when in use all of the systems of language together support the reading and writing process.

Conclusion

Viewing the reading and writing connection from a process perspective, as authoring, has constituted one of the biggest breakthroughs in our understanding of English-language learning (Pearson & Tierney, 1984; Harste & Short, 1986; Short & Harste, 1996). While there are parallels at the graphophonic, structural, semantic, and pragmatic levels of language, seeing reading and writing in terms of "processes of mind" makes these connections even

clearer. Both readers and writers build from their background of experience to make predictions in reading and to get some thoughts down on paper in writing. During both processes revision is necessary, with meaning or semantics being the driving force. By sharing what one has read or by sharing a first draft in writing, others collaborate in meaning making by asking for clarification or by sharing insights they have on the topic being discussed. Revision, in both reading and writing, often happens both on the page and off the page. For the writer constant reading and rereading is a must. For the reader, composition is an ongoing process, even long after the eyes have left the page. No one rereads a book the same way after once having had a discussion with someone about what was initially read. The text is richer just as is the text in writing after collaboration, reflection, and recomposition. Pragmatically one can see these processes as repositioning oneself in one's world. And it is from this repositioning that a new level of authoring begins.

Realism

ALISON SEALEY

"Realism" is a term with a range of meanings in a number of academic disciplines. It is not a research method but a philosophical orientation, and even within philosophy "the word 'realism' is used in a bewildering variety of senses" (Williamson, 1995, p. 746). "*Naïve*" or "*commonsense*" realism is the belief that what we perceive through our senses is real and that objects have the properties which they appear to have. More sophisticated forms of realism recognize a more complicated relationship between the world as it appears to us, the world as it might possibly be, and the knowledge we can have of the relationship between these. The core of the philosophical issue is whether there is an objective reality independent of human perception. Realists maintain that entities which are mind-independent do indeed exist: this is an *ontological* claim—about the nature of reality—and not an *epistemological* claim about how we can gain knowledge of that reality. Metaphysically, then, realism is "a thesis about what the world is like, . . . not a semantic thesis concerned with how humans represent the world in thought or language" (Khleutzos, 2008).

These claims raise some obvious questions, including this one: since we can only ever know the world through human perception, what warrant can we have for asserting the existence of entities beyond those perceptions? Realists have commonly sought to answer this by asking a further question, namely: what must reality be like for us to have knowledge of it? In other words, for realists, theories are always about a reality beyond the theory, in light of the belief that our theories are constrained by the nature of the things we are trying to understand. This means that not all theories are equal. "[R]ealists differ from strong social constructionists in their claim that it is possible to make rational (though fallible) judgments about the relative value of competing theories, models and concepts" (Olsen, 2004, p. 136). Realists recognize that we do not have full, direct access to reality, and that human knowledge is necessarily partial, fallible, and mediated through language and other semiotic resources. This, however, does not lead them to conclude that there is no extra-discursive reality. As Sayer expresses it (1992, p. 83), "The world can only be understood in terms of available conceptual resources, but the latter do not determine the structure of the world itself." The belief that they do is referred to as the "epistemic fallacy." Realism, in its insistence on an extra-discursive reality, is opposed to many forms of relativism and to theories which see social reality as constituted wholly by representations and discourses. *Critical realism*, closely associated with Bhaskar, stands in opposition to "cognitive relativism and irrationalism or superidealism" (Hartwig, 2007a, p. 97), identifies itself as emancipatory, and in its strongest form posits "the real existence of *dialectically* universal rights to truth (learning) and freedom at the level of the real" (Hartwig, 2007a, p. 103, italics in original).

Realist approaches are usually allied with some form of naturalism (Bhaskar, 1979, 1998). In principle, both natural and social reality can be analyzed using broadly similar methods. Social realists are skeptical about the extent to which even the natural world is uniformly subject to governing laws, believing that it is more accurate to think in terms of tendencies—"the likelihood of certain things occurring, given certain sorts of conditions (Bhaskar, 1979, pp. 1–21)" (Carter & New, 2004, p. 2). Furthermore, the social world is understood to include things which are qualitatively different from the components of the nonhuman world.

Research into both seeks causal explanations, but “[t]he complexities of human ambition, desire, interests and relationships are such that social relationships could never be reduced to a set of unchanging generalizations” (Carter & New, 2004, p. 1).

Realists, particularly critical realists, subscribe to the concept of a “stratified ontology,” and the distinguishing feature of realism in social science, in a tradition that can be seen in the theories of Marx, Durkheim, Habermas, and Bourdieu, has been its insistence on the reality of structured social relations. Social structures are enduring, often over longer timescales than the human life span, and constitute a significant aspect of the contexts into which people are born. They are the result of human activity, but have “independent effects of their own—even apart from agents’ knowledge of their existence. Examples include [material] relations that—even without agents’ knowledge—are exploitative or that otherwise place agents’ interests in conflict” (Porpora, 2007, p. 425). The “structure” aspect of society is analytically distinct from “agency.”

Structured social relations provide the already-existing contexts which people encounter, and these may constrain or enable the projects they seek to pursue. Among the properties of human beings are intentionality and reflexivity. That is, as people we have the power “to self-consciously monitor our activities and deliberate internally upon the always already natural, practical, and social context in which they occur” (Hartwig, 2007b, p. 408). As acknowledged in Marxism, people make history, but not in conditions of their own choosing. The products of human consciousness and reflection give rise to culture: the “Cultural System,” consisting of interlinked propositions, and “Socio-Cultural life,” or “the stuff of Socio-Cultural interaction” (Archer, 1988, p. vxii).

Realism sees both structure and agency as causally efficacious; that is, people cause things to happen, but so too do structures: “by motivating or discouraging, constraining and enabling certain sorts of human action” (Carter & New, 2004, p. 12). This realist, stratified ontology is contrasted with the “downward conflation” of structural determinism, the “upward conflation” which envisages society as nothing but the collective result of the actions of individuals, and “central conflation,” which presents structure and agency as mutually constitutive, precluding the possibility of exploring the effects of one on the other (Archer, 1995). In other words, “to reduce power, institutions, organizations and the distribution of various resources to local practices is to confuse and conflate very different kinds of social phenomena” (Layder, 2005, p. 108).

One further key concept of realist social theory is emergence. “Emergence is the idea that a whole can have properties (or powers) that are not possessed by its parts” (Elder-Vass, 2007, p. 28). Some entities, substances, properties, or systems are dependent for their existence upon other entities, substances, properties, or systems, but emergent properties are not reducible to their constituent parts. For example, emergentists “argue that human individuals, although composed of their biological parts, have causal powers of their own, which cannot be reduced to the powers of their biological parts” (Elder-Vass, 2007, p. 27). Reflexivity is one such emergent property “irreducible to the social or the biological” (Hartwig, 2007b, p. 408).

Methodologically, realism is not prescriptive, recognizing that there are many practical ways in which phenomena may be investigated. Nevertheless, the ontological claims accepted by realists have clear implications for research methodology. One implication of these distinctions is that the empirical study of any aspect of the social world should avoid the conflation of structure and agency, and allow for the recognition of their respective properties and powers. For example, social structures can provide contexts for, and exert influence on, social interactions, but they are not subject to empirical investigation in the way that conversations are. Likewise, human beings’ capacity for reflexivity makes it inappropriate to try to study them in the same ways that unreflective entities (such as cells or stones) may be studied. Epistemologically, realists distinguish between

the “transitive” effects of human agency (of experiment, controlled observation, technological expertise, carefully contrived laboratory set-ups, and so forth) and the “intransitive” dimension of a physical reality which must be taken to exist and exert its causal powers quite apart from [the] scope and limits of our knowledge. (Norris, 2007, p. 337)

The study of language from a realist perspective has taken various forms, and is relevant to a wide range of areas of linguistic and applied linguistic theory and method. Many kinds of research in the linguistic disciplines are consistent with a realist philosophy, whether or not this is declared explicitly in the research design or reports of findings.

The nature of language itself has been conceptualized within a stratified ontological framework. The concept of a universal grammatical system as a “deep” structure is consistent with that tenet of realism which maintains that what can be observed does not exhaust what is. One does not need to be able to observe directly the language acquisition device proposed by Chomsky (1965) in order to accept that some such configuration, as an evolved biological endowment of the species, may be the best explanation for human beings’ capacity to acquire language. In this sense, Chomskyan conceptions of language may be classified as realist, although they have been criticized by critical realists as biologically reductionist (Jones, 2003, p. 280) and conflationary (Archer, 1988, p. 39). Other realists have suggested that languages are themselves cultural emergent properties. The speakers of human languages (as embodied entities with the innate capacity to communicate by means of sounds produced and received using the material, biological resources of the vocal and aural systems) develop actual linguistic systems over time and through social interaction, and these are understood as examples of emergence (Sealey & Carter, 2004). This conception accords with those emergentist accounts of language acquisition which “hold that linguistic form arises from interactions between the shape of the body, cognitive processing, and the nature of social interaction across a wide variety of timescales” (MacWhinney, 2006, p. 732). The conception of languages as complex systems (e.g., Larsen-Freeman, 2002; Larsen-Freeman & Cameron, 2008) is potentially consistent with realist theory, although there are some differences between these perspectives. Sealey and Carter (2004) argue that because actual human languages are not reducible to their component parts, constituting, as they do, an aspect of “culture,” they have the causal power to “act back” on speakers by dint of the ways in which they shape what can be said and recognized as intelligible by other speakers. This kind of causal power is illustrated by the phenomenon identified as “semantic prosody” (Louw, 1993). When a speaker selects a word which is in itself nonevaluative, but is routinely used of negatively evaluated entities or processes, the word is “colored” with this negative evaluation and will be perceived in this way by other speakers of the variety. Findings such as these are readily accommodated within a realist framework, despite the fact that the researchers associated with them may declare themselves unconvinced by, or even hostile to, realism.

Similar observations can be made about many other areas of empirical research into language. Corpus linguists, for example, do not need to subscribe to a realist philosophy in order to carry out technologically assisted studies of large quantities of authentic language data and identify hitherto unnoticed patterns linking vocabulary, grammar, and the relations between them. However, the findings from such research are readily interpretable as examples of the emergent properties of structure, agency, and linguistic cultural resources. Seen from a realist perspective, corpus studies help to demonstrate how speakers make discourse and contribute to the existing discourse contexts which subsequent speakers encounter. Speakers make linguistic choices, but can only choose from the linguistic resources available to them, and not all speakers are equally placed to contribute to the forms of utterance—and writing—which are valorized and transmitted to subsequent generations of speakers.

Researchers who are concerned with language policy on a macro scale and the dominance of English in global communication study such phenomena from a variety of philosophical perspectives. A realist orientation precludes affording a linguistic variety agential powers (so would not, for example, include descriptions of “English” itself as “imperialist”). Rather, it invites exploration of such phenomena with reference to people, social structures, and cultural resources. People are conceived of as both agents with interests—as members of “*collectivities sharing the same life chances*” (Archer, 1995, p. 257, italics in original)—and as individuals with projects and goals, while the cultural resources on which they can draw (including access to linguistic varieties) are differentially distributed.

Applied linguistic research into language teaching and learning also encompasses a wide range of philosophical perspectives, associated with various research methods. Investigations that are compatible with a realist ontology acknowledge the social world as an open system and do not try to transfer methods appropriate for studying unreflective entities to the study of reflexive human beings. For example, as explained by Danermark, Ekström, Jakobsen, and Karlsson (2001, p. 67), experiments are “artificially closed systems” which “in the natural science sense of the term are not possible for social science.” Thus to “subject” one group of learners to a “treatment” of one kind of teaching and another group to a different one, and then compare results, is for a realist misguided, because people have the properties of self-conscious adaptation. They therefore cannot meet the criterion, for experimentation, of closure, which requires “that there must not be any change or qualitative variation in the objects [studied]” (Danermark et al., 2001, p. 68).

Any research design that depends on the concept of social “variables” is, from a realist perspective, similarly suspect. Byrne (2002, p. 31) maintains that “variables don’t exist. They are not real.” His alternative explanation for the tendencies of certain outcomes to correlate with certain attributes is to identify the causal mechanisms of which such patterns may be the empirical traces. A mechanism is “not . . . a single *variable* but an *account* of the constitution and behavior of those things that are responsible for the manifest regularity” (Pawson, 1989, p. 130, italics in original). And, since causal powers inhere “not simply in single objects or individuals but in the social relations and structures which they form” (Sayer, 1992, p. 105), research design consistent with these claims is more holistic, seeking to identify the operative mechanisms and the contexts and circumstances within which they are causally effective.

Of the applied linguists who reject research methodologies based on variables and experiments, many use qualitative, interpretative methods in an effort to capture meanings and perspectives unavailable by other means. Again, methods such as observations, interviews, ethnography, and so on can all be deployed by researchers working within a realist framework. The distinctiveness of a realist approach is that interviews, for example, are understood not simply as discursive versions of the social world, intersubjectively “constructed” by researcher and interviewee, but as accounts, however partial, of actual experiences, of situations which exist independently of participants’ perceptions of them. At the same time, and for the reasons outlined above, participants’ accounts cannot provide information about those aspects of the social world which are more remote and opaque from direct perception. This makes it very likely that other methods will be needed to supplement interviews.

Finally, those applied linguists who explicitly identify themselves as realists are developing research approaches within the discipline. Probably the most prominent is Norman Fairclough, whose later accounts of critical discourse analysis root it in critical realism (CR) (e.g., Fairclough, Jessop, & Sayer, 2003). Other explicit applications of realist philosophy in applied linguistic research are found in the publications of authors such as Belz (e.g., Belz, 2002), Corson (e.g., Corson, 1997), and Sealey (e.g., Carter & Sealey, 2000, 2004; Sealey & Carter, 2004; Sealey, 2007, 2010).

Receptive Multilingualism

DARIA BAHTINA AND JAN D. TEN THIJE

Concepts of Receptive Multilingualism

Receptive multilingualism refers to language constellations in which interlocutors use their own language while speaking to each other. This mode was widely applied in the Middle Ages, but linguistic constellations were transformed into monolingualism determined by nation-state formation from the 17th to the 19th century. Mainly due to areas and countries where receptive multilingualism still flourishes, researchers have demonstrated increasing interest in the processes behind this type of multilingual communication. This entry first discusses the theoretical concept of this phenomenon and then describes historical developments, linguistic and mental characteristics, as well as current applications.

The discussions of the phenomena date back to Voegelin and Harris's "intelligibility" (1951) and Bloomfield's "dialect continuum" (1933). Close genetic relationship was claimed to enable inherent comprehension between dialects. Similar studies on mutual intelligibility were carried out in the 1950s and 1960s (e.g., Wolff, 1964). Intelligibility of closely related languages has been discussed from the Scandinavian perspective by introducing the notion of *semi-communication* (Haugen, 1953). The author claims that intelligibility occurs both on the surface level and on the level of mental processes of understanding. On the surface level, similarity can occur in linguistic forms, such as syntax, lexicon, or morphology, thus understanding requires little education or practice in that other language. Yet this definition implies incomplete communication, in which only "half-understanding" is reached.

The concept has been transformed in the direction of "successful" language mode, bringing along other alternatives, such as plurilingual communication, intercomprehension, and receptive bi/multilingualism. The idea of *plurilingual communication* applies to societal multilingualism (e.g., Switzerland) and to comprehension strategies, since intelligibility comes from individual plurilingual repertoires (Lüdi, 2007). Next, *intercomprehension* covers a similar domain when receptive skills are activated, but generally between typologically related languages (Berthele, 2007). *Receptive multilingualism* has been addressed in a number of studies (Zeevaert, 2004; Braunmüller, 2007; ten Thije & Zeevaert, 2007), where the concept is expanded by inclusion of typologically distinct languages and application of hearer-oriented activities.

Other dimensions that have been reflected upon in relation to the use of this mode are awareness of intelligibility, experience in how to apply this knowledge in multilingual communication, attitudes toward the languages involved, and availability of agreement to apply this mode. Haugen constructed the concept of semi-communication on the premises that interlocutors strongly depend on their experience and have to learn to understand the language of the other (Haugen, 1953). Similarly, Braunmüller (2007) in his studies emphasizes that awareness of the interactants concerning the mutual intelligibility of languages plays an important role. Next, ideological factors affect attitudes which in their turn can either enhance or block comprehension between communities and languages within a constellation. Finally, application of this mode might depend on institutional language policy or explicit personal agreement of social actors, or a shared communicative history, such as "discursive intercultural" (Beerkens, 2010).

“Lingua receptiva” (LaRa), in contrast to previous research, has been introduced by Rehbein, ten Thije, and Verschik (2012) in order to emphasize the receptive component. According to the definition, “*lingua receptiva* is the ensemble of those linguistic, mental, interactional as well as intercultural competencies which are creatively activated when interlocutors listen to linguistic actions in their ‘passive’ language or variety” (Rehbein et al., 2012). To enhance understanding of lingua receptiva, this concept can be compared to that of lingua franca, since both function as vehicular languages. The important distinction is that in the case of lingua franca the languages are non-native, whereas in the case of lingua receptiva the status of the language is not defining. In LaRa, interlocutors speak their L1 or any other language they are comfortable with.

Communicative Constellations of Receptive Multilingualism

The occurrences of receptive multilingualism appear to be manifold. In the late Middle Ages and early modern times, the situation in Europe and Scandinavia was complex and diglossic. Braunnüller (2007), among others (Börestam Uhlmann, 2001; Zeevaert, 2004), gives an overview of a pan-Scandinavian movement that propagated receptive multilingualism. A similar development took place in Europe when face-to-face trading interactions maintained the idea of successful communication with partial competencies in several languages. Rindler-Schjerve and Vetter (2007) documented the language-political situation in the Habsburg Empire with receptive multilingualism being the official ideology. Upon the disintegration of the empire, Europe was gradually absorbed in the idea of nation-state ideologies that replaced “imperfect” multilingualism with monolingualism in all social institutions.

Currently, the European language situation is being shaped by various processes such as globalization, decolonization, migration, and overall mobility. This postnational situation challenges the nation-bound concepts of language and leads to various potentially conflictual multilingual constellations. As a consequence, more attention is being paid to various models of multilingual communication. The European Commission promotes the maintenance of the 23 official languages in Europe so that all European citizens learn at least two languages in addition to their mother tongue. Receptive multilingualism could be a way to achieve that goal and the High Level Group on Multilingualism (2007) suggests research into various institutional settings.

Recently, studies on receptive multilingualism have focused on the following domains: border regions (Beerkens, 2010), institutional discourse (e.g., Ribbert & ten Thije, 2007), media (e.g. Nábělková, 2008), educational settings (e.g., Zeevaert, 2004), sales talk and business communication (e.g., Lüdi, 2007), written-text comprehension (Bezooijen & Gooskens, 2007), cross-generational and family discourse. The language constellations that have been studied so far list European language families, such as Romance, Germanic, and Scandinavian, Slavic languages, Finno-Ugric, Turkic languages, Indo-Iranian and Semitic languages, as well as diverse combinations that include constellations across language families.

Mental Processes of Receptive Multilingualism

Receptive multilingualism, as the name suggests, treats receptive competencies of the hearer as one of the two essential dimensions of this mode. Previous research on multilingual communication mainly concentrates on speaker competencies and activities. Therefore the following section elaborates on hearer activities, such as accommodation, alignment, and the metaphor of “inference-making machine” based on multilingual

repertoires.

Hearer and Speaker

On the linguistic surface level, hearer-oriented activities list all the processes that actualize and intensify the hearer's competencies, such as nonverbal and prosodic signals that steer the speaker's production, formulaic expressions signaling potential misunderstanding, echo questions, and other linguistic elements. Specific speaker activities within the receptive mode are exemplified by reformulations, repairs, recapitulations, rephrasing, and other types of metadiscourse elements (see, e.g., Rehbein & Kameyama, 2003). Other accommodation strategies contain slower and more accentuated pronunciation (Zeevaert, 2004).

The stages of understanding in receptive multilingualism can be reconstructed by applying the speaker and hearer plan (Rehbein & Kameyama, 2003) that describes mental steps in a hearer's perception. Recently this plan has been adapted to account for accommodation processes (Beerkens, 2010) that refer to the assessment of an interlocutor's L2 competencies as one of the crucial stages in the process of receptive understanding. These stages clarify processing in general and unveil a switch between perception in one language and production in the other, the so-called "turnover" moment. Accommodation can be ascribed to the field of sociolinguistics (Braunmüller, 2007), whereas alignment is a notion that describes similar processes from a psycholinguistics perspective. Alignment occurs when interlocutors adapt both linguistically and conceptually in order to enhance understanding (see, e.g., Pickering & Garrod, 2004). Adaptation can take the form of phonological, lexical, semantic, syntactic, or pragmatic convergence. In monolingual speech these processes are often automatic; in multilingual communication alignment could be used to ensure mutual understanding. Moreover, the turnover between languages is less complicated once speaker and hearer have activated similar structures (e.g., words or constructions) in their respective languages.

Inference-Making Machine

Another type of mental activation relevant for receptive multilingualism is the inference-making machine. This "inference-making machine" is claimed to connect seemingly unconnected utterances by activating linguistic and other types of knowledge (Sacks, 1985). The same processes are applicable to receptive multilingualism, for instance the notion of "wholistic" activation in bilinguals (Grosjean, 2008) or the concept of linguistic repertoires (e.g., Lüdi, 2007). Both theories presuppose simultaneous application of diverse plurilingual resources within individuals and thus non-compartmentalized (i.e., separate) use of the languages involved. In receptive multilingualism mutual familiarity with common speech formulas (i.e., idiomatic expressions, the ritualized and repetitive side of language) facilitates understanding between languages and varieties. In addition to linguistic and world knowledge, inferencing relies on common institutional and discourse-type (i.e., genre) knowledge. "Perceived language distance" or psychotypology (Kellerman, 1995) can either trigger or hinder activation of the inference-making machine, since interlocutors tend to have intuitions about the distance between languages involved. Interlocutors who use typologically close languages might be more aware of cognates (i.e., words that are recognizable across various languages) or similar syntactic structures in multilingual communication and thus be more effective in reaching understanding. The same applies to written discourse (Berthele, 2007), when readers show better performance when dealing with cognates or homographs and homophones (graphically or acoustically similar words). To sum up, both hearer and speaker profit from making inferences from all the resources of the languages involved in a communicative situation, as well as from other languages available in their linguistic repertoires.

Receptive Multilingualism Applied

Receptive multilingualism in the globalized world has been acknowledged as a means of language policy that supports language diversity and maintenance both top-down (High Level Group on Multilingualism, 2007) and bottom-up (Beerkens, 2010). The latter refers to a wide range of communicational settings where individual interlocutors or groups of people choose receptive multilingualism to effectively cope with the barriers of multilingual communication. Top-down developments, on the other hand, denote language policies that have been installed in order to manage linguistic diversity. Various European research projects on multilingualism have established a set of didactic concepts that either integrate receptive multilingualism in general language teaching (see the GalaNet and GalaPro Web sites at www.galanet.eu and www.galapro.eu) or develop language-specific strategies that aim for receptive competencies within those languages (see the EuroCom Web site at www.eurocomresearch.net). The GalaNet project has developed strategies of intercomprehension aimed at discovering plurilingualism as well as promoting comprehension skills among speakers of different languages, specifically among speakers of typologically related languages. The GalaPro project delivers online courses for teachers based on the GalaNet platform in order to cooperate in multilingual (French, Spanish, Italian, and Portuguese) educational settings. The EuroCom project provides several frameworks where similarities between typologically close European languages are compared in order to be made more accessible in multilingual communication. Romance, Germanic, and Slavic languages have been structured into “seven sieves” that are already available to speakers of those languages. According to EuroCom, Romance languages comprise the following elements as “sieves”: international and pan-Romance vocabulary, sound correspondence, spelling and pronunciation, syntactic structure, morphosyntactic elements, and Latin-based suffixes and prefixes. Another line of applied research focuses on development of a learner’s grammars from a hearer’s perspective, such as ‘Rezeptive Grammatik’ for learners of German (see, e.g., Berthele, 2007). All these projects concentrate on acquisition of languages that are related yet different. Similarly, receptive knowledge of dialects has led to the establishment of didactic materials for constellations like German and Swiss German (Müller et al., 2009).

To conclude, receptive multilingualism represents an ensemble of multiple competencies that are applied by the interactants both in speaker and in hearer position. Interlocutors in this mode draw on the inference-making machine and available plurilingual repertoires (between languages that are typologically close or genetically unrelated). Historically, receptive multilingualism has been and still is an effective mode in various plurilingual constellations. This mode has therefore been rediscovered as a means of solving potential communicative problems and is already effectively applied in educational and other institutional settings.

Register

JENS ALLWOOD

Linguistic Variation

The fact that there are systematic differences between the ways in which people speak, write, and gesture in different parts of the world has led to a great number of concepts and terms having been proposed to capture this variation. Here is a nonexhaustive list: language, dialect, sociolect, register, sublanguage, activity language, restricted language, trade language, scientific language, text type, accent, “patois,” jargon, slang.

All these terms focus on different aspects of linguistic variation. Some focus on the nature of the social group or institution that is viewed as a basis for the variant (e.g., nation, ethnic group—“language”; regional area—“dialect”; social class—“sociolect”; individual personality—“idiolect”). Others focus more on the purpose for which the variant exists (e.g., social activity—“activity language”; “sublanguage”; “genre”; “trade language”). Some, like “accent” or “text type,” focus on what aspects of language are involved and some, like “jargon” or “slang,” incorporate an evaluation of the language variety (in the case of “jargon” and “slang,” usually negative).

So what are the distinctive features of the term “register” as a way of capturing linguistic variation?

What Is a Linguistic Register?

The term “register” is a fairly new term for a linguistic variant and seems to first have been used by Reid (1956, p. 32), perhaps inspired by J. R. Firth’s notions of “situational category” and “restricted language” (see Léon, 2007), later picked up by Halliday, McIntosh, and Stevens (1964, pp. 174–5) and Trudgill (1983). It is based on an attempt to make a distinction between linguistic traits due to properties of the “user” (i.e., properties like regional background, social class, age, and sex) and “register,” that is linguistic traits dependent on the “use” or “usage,” where these traits are often produced by adaptation to properties of the situation of use, for instance adaptation to other speakers (e.g., being ingratiating or stern), to the purpose of what is being communicated (e.g., a persuasive vs. a humorous style), to the topic (e.g., the weather vs. politics), or to the occupation or role of the speaker in a particular activity (e.g., speaking as a teacher in a classroom or as a customer in a shop).

The distinction between “properties of the user” and “properties of use” is perhaps not totally clear and one might object to it by arguing that people can move from one country or region to another and change their language or dialect accordingly, and that they can move socially—be “social climbers” or “social descenders”—and change their sociolect. (This is also true for the social-class-related registers distinguished in relation to so-called creole language continua, i.e., “acrolect,” “mesolect,” and “basilect.”) As people grow older, they change their age-dependent ways of speaking for biological reasons. They may even change their sex and thus perhaps change their gender-dependent ways of speaking. In addition, one may argue that not only is it possible for a person to change his or her

language, dialect, sociolect, or age- or sex-dependent ways of speaking, but in fact it is also possible to learn all of these linguistic variants, and that many, perhaps most, people actually do learn several such variants and thus become multilingual, multidialectal, or multisociolectal speakers. Some even learn the variants of different age groups or can change to the language of the other sex. As a consequence of this, there are many examples that show how “user-dependent” types of linguistic variation can also be used for situational adaptation. All this means that, strictly speaking, the distinction between “user-dependent properties” and “usage-dependent properties” is difficult to uphold, if one believes that the user-dependent properties are unchanging and cannot be intentionally adapted to a particular situation.

However, since it seems useful to be able to distinguish different types of linguistic variation, the distinction might still be upheld if conceived of in a slightly different (and stipulative) way as follows: The term “register” will be used for features that are associated with profession, social activity, rhetorical style, subject matter (topic), emotional-attitudinal style, and so on (see below), and not for linguistic properties which are associated with a language (mostly based on nation or ethnic group), dialect (regional domicile), sociolect (social class) or idiolect (person), or age- and sex-dependent properties of language. A “register” is thus a set of linguistic features which are used for a particular function or purpose (excluding the purpose of trying to indicate membership in the above-mentioned groups), mostly produced in a specific social role, social activity, or profession.

Given this characterization, “register” as a concept comes close to and overlaps with terms like “sublanguage,” “trade language,” “genre,” “restricted language,” “activity language,” and “text type.” One difference is perhaps that “text type” and “genre” tend to be more associated with written language, while “register” often is more open to spoken language. The reason for the overlap between the terms derives from the fact that different authors with slightly different perspectives and backgrounds have discovered the situational and purpose-motivated linguistic variation we have described above and then attempted to describe it using terms associated with their own perspective. Some authors have tried to define and stipulate a difference between some of the terms (see Trosborg, 1997, p. 9, for an attempt to differentiate register, genre, and text type), while most authors either settle on one of the terms as generic or treat the terms as loosely associated, more or less synonymous, terms. See Biber (1988) and Biber, Conrad, and Reppen (1998) for an example of an author who in 1988 uses “genre” as a generic term for all the varieties he is studying and in 1998 uses “register” for more or less the same purpose. Whatever term is used, the linguistic variation that is intended to be captured by the term “register” has become an important source of inspiration in corpus linguistics (see, e.g., Biber, 1988, 2006; Biber et al., 1998; Trosborg, 2000; and Aijmer & Stenström, 2004).

Examples of “register” that have been mentioned are “motherese,” “legalese,” “news reporting language,” “medical language,” “engineering language,” “persuasive,” “phatic,” and so on. Other examples might be the register of persuasion, the register of seduction, the register of teaching, advertising, preaching, or interrogation.

Types of Register

The examples of “register” that have been given above show that a register may be based on many different factors that are not necessarily mutually exclusive. One attempt to systematize the factors that determine a register has been made by Halliday (see for example Halliday et al., 1964, and Halliday, 1978), who claims that these factors can be summarized through the concepts “field” (mainly the activity type and subject matter or topic associated with a particular use of language), “tenor” (the relations, mostly given by social roles, between the communicators), and “mode” (including the difference between

spoken and written language, between dialogue and monologue, and between different rhetorical modes such as didactic, persuasive, and so forth). Some possible types of linguistic register are given below.

Professional Register

A professional register is made up of the common linguistic traits associated with the practicing of a particular profession—compare for instance the registers of lawyers, doctors, carpenters, dentists, politicians, academics, psychologists, historians, shoemakers, welfare workers, plumbers, tax collectors, civil servants, teachers, priests, accountants. The professions in the list are on different levels of abstraction, which indicates that the different professional registers may have properties in common. For example, lawyers, doctors, psychologists, and historians are all academics and their registers might thus have something in common. Similarly welfare workers and tax collectors are civil servants, and their registers might for this reason have common traits. Carpenters, plumbers, and shoemakers are craftsmen and might accordingly have other common traits. Some professions involve collaboration with clients or with other professions and might in addition to their own register pick up traits from the registers of the persons they work with, so lawyers and accountants might be influenced by their clients, teachers by their employers or students, or politicians by their voters.

A special type of professional register is associated with magic or religion. In many cultures, such registers can be very elaborate but still be limited to select members of the community. As another special case of professional registers, we can perhaps also include argots and so-called cryptolects (i.e., linguistic variants that are secret or difficult to have access to for the noninitiated).

Activity Register

The traits that can be associated with the language used in a particular social activity (see Allwood, 2000) can be called an “activity register.” Examples of social activities in this sense are: meetings, negotiations, patient–doctor consultations, planning, interrogations, joking, quarrels, teaching, instruction, interviews, small talk, sermons, lectures, storytelling, giving advice, confessions, trials, lawyer–client consultations. Social activities can be distinguished from professions since a given profession usually involves participating in several different social activities. A lawyer can, for example, participate in a trial, in a consultation with a client, in a negotiation with an adversary, in planning with colleagues or in small talk with colleagues. A doctor can similarly have a consultation with a patient, have a planning meeting with colleagues, make small talk with other medical staff, and so on. A profession is, thus, typically characterized by a number of activities that are involved in carrying out the tasks of the profession. Often, these activities involve the use of a specialized activity register, for example tax law rather than law in general, the requirements of which go beyond the register that is more generally part of the profession.

If we examine the types of social activities exemplified above, we can see that, just as in the case of professions, they overlap and occur at different levels of abstraction. For example, negotiations and planning are both kinds of meetings and might, for this reason, have features in common. Patient–doctor consultation and lawyer–client consultation are both consultations and probably both involve giving advice, and they might thus have features in common. Interrogations and interviews are probably similar in several ways, as are teaching and instruction. Some activities are perhaps fairly unique, like a sermon or a trial, but we can see that a trial is also a kind of meeting and that even sermons and lectures are meetings of sorts, despite the fact that they all often involve a larger amount of one-way communication than is common in other meetings.

4 REGISTER

Another feature of the communication and language in a social activity is that it might be multifunctional, either sequentially or simultaneously. Thus a negotiation can simultaneously be a quarrel or a planning meeting and involve joking. The reason for this is that various terms for social activities and registers focus on distinct properties of interaction that can be simultaneously or sequentially present in a given interactive process. What this means is that specific occurring behaviors can sometimes be related to several registers and thus be multifunctional. For example, a loudly spoken claim can be part of the register of negotiation and the register of quarreling simultaneously.

Registers Depending on Topics, Roles, Rhetorical Purposes, and Emotional-Attitudinal Moods

Below are some examples of these types of registers:

Topics: Different topics have different vocabularies, perspectives and perhaps different grammatical constructions. Compare the topic-related registers of history, weather, medicine, and engineering.

Roles: Different roles in a family have different registers, for example “motherese,” “fatherese,” and perhaps “grandmotherese” and “grandfatherese.” As we have seen above, roles can also be taken in the sense of a professional role or an activity role and thus be part of what determines the register of activities and professions.

Rhetorical purposes: Different rhetorical purposes like admonishing, being stern, seductive, or persuasive are connected with different registers.

Emotional-attitudinal moods: These are registers such as that of a quarrel, of a commiseration, or of a humorous, jocular interaction.

Covariation of Different Types of Register

Let us now examine the relationship between registers and some of the other types of linguistic variation not associated with nation, region, social class, or individual personality. Perhaps they can be grouped as follows, according to their main conceptual orientation and allowing for a certain overlap between them (the list of different possible registers is not meant to be exhaustive but merely to exemplify the types):

1. professional register (often overlaps with topic register), for example legalese, medical language, engineering language, jargon (negative evaluation of a professional register);
2. activity register (often closely connected with professional language and includes the register of particular activity roles);
3. rhetorical register, for instance persuasive, ingratiating, seductive, stern, humorous, apologetic, or phatic;
4. other registers (based on family, emotions-attitudes, evaluation, informality), for instance “motherese,” baby talk, “fatherese,” joking, quarrel, formal, casual, intimate, jargon, slang.

Activity registers and rhetorical registers can additionally perhaps be subdivided as follows, according to whether they are oriented to spoken language or written language, or neutral in this respect:

1. spoken registers, for example instruction, teaching, lecture, preaching, sermon, interrogation, interview, confession, lawyer–client consultation, trial, auction, giving advice, patient–doctor consultation, negotiation, planning, meeting, small talk, conversation;

2. written registers, for example genre, text type, advertising, cookery books, headlines, scientific articles, textbooks, novels;
3. neutral registers, for example style, activity language, sublanguage, trade language, news reporting language, narrative, poetic.

Two of these terms, “genre” and “text type,” deserve special interest, since they are sometimes used in a generic sense, similarly to the way we are using “register” here. Both terms, besides having a more written-language orientation than “register,” are also oriented more toward a lasting result of the communication than “register” (i.e., a certain kind [type] of text, e.g., a cookery book, a law book, a volume of poetry). “Register,” in contradistinction, is less oriented to the end product and more oriented toward a particular type of linguistic competence, the use of which leads to the end product. Perhaps this is a consequence of one of the conceptual origins of “register” being the Firthian notion of the “linguistic repertoire” of a particular person (see Léon, 2007). For genre and text type, the end product—the type of text—is primary, even if secondarily we might also include the competence required to produce the genre or text type.

What Linguistic Features Can Be Part of a Register?

Some authors have wanted to restrict the linguistic features that constitute a “register” to vocabulary differences (e.g., Trudgill, 1983), while others have taken a more inclusive stance, in principle allowing for “register” to cover any linguistic features, which could mean that any phonological, morphological-lexical, syntactic, pragmatic (e.g., rhetorical), or gestural (“gesture” is here taken in the wide sense of a communicative body movement) trait that can be systematically associated with a purpose, social role, social activity, or profession could be taken as part of a register.

In principle, all properties of language that can be analyzed can automatically be compared with regard to register, if we have access to a computer-based corpus consisting of different written language texts or transcriptions of spoken language containing several registers. Some examples are:

1. frequencies of words, utterances, pauses, overlaps, collocations, phrases, sentences, and so on;
2. stereotypicality (number of duplicates or repetitions of words or collocations);
3. average word length, utterance length (mean length of utterance, or MLU);
4. vocabulary richness measures;
5. frequencies of different parts of speech.

For other examples see Biber et al. (1998) or Biber (2006).

Some Examples of Grammatical Register Features

Some examples of registers that have distinctive grammatical features are given below. We may here note that some of the differences that can be observed between the grammatical constructions of different registers are due to mere convention, while other traits can also be related to functional factors in the activity that the register is related to.

The register of *headlines*: A complete and grammatical headline can consist for example of a noun phrase (NP), like *The home front*, or a prepositional phrase (PP), like *After the party*, or of a nominalization with a PP, like *Singing in Turkey*. Complete headings often

lack subject or predicate verbs. In headlines there is often a lack of space, which leads to focusing on the most striking content features in order to catch attention.

The register of *scientific articles* often includes frequent use of passives and impersonal constructions, like *It was demonstrated that*. Scientific language also often uses fairly complex nominalizations; this leads to a use of abbreviations, such as *fMRI* (brain scanning: functional magnetic resonance imaging) or *NaCl* (chemistry: potassium chloride). A side effect of this is that sometimes scientific articles become less accessible to persons outside a particular scientific field, who do not understand the abbreviations. This may in turn be sometimes desirable and sometimes less desirable. It is often important to appear objective; this leads to a focusing on the object of inquiry in order to direct attention away from the subjective evaluations of the author. According to Biber (2006, p. 64), the passive voice is used overall in 20% of academic texts, compared to only 5% of the transitive verb phrases in spoken conversation. Part of the explanation is that the passive voice allows focusing on natural processes, while defocusing the agent involved in observing or creating the process. There is some variation between the written texts of different disciplines. Engineering textbooks use the passive in almost 30% of all verb phrases, while the percentage is lower in the humanities and social sciences.

Cookery books can include frequent use of imperative forms and measurements, for instance “Beat egg whites stiff. Gradually add $\frac{1}{4}$ cup sugar, beating constantly. Cream together shortening and remaining sugar” (from Woody, 1942, p. 71). The purpose of cookery books is to give instructions in how to prepare food. One way to do this is to use imperatives and another feature is to use measurements, so that interested readers will know what quantities of different substances to use.

The language of *auctions* includes frequent complete utterances consisting of numerals. The purpose is to sell objects at as high a price as possible. This naturally leads to a focus on numerals indicating the current bidding level of the object being sold. It is here interesting to compare the language of bingo games, which, for slightly different reasons, also contain utterances often consisting only of numerals.

Since different registers to some extent involve different subject matter and topics, perhaps the most easily detectable differences between registers concern vocabulary, although more grammatical features also occur, like differences concerning parts of speech or differences in sentence or clause type.

Some of the most striking differences between registers are correlated with the difference between spoken and written language. This can be seen, for example, if we consider the distribution of the parts of speech for spoken and written registers (see Table 1, which compares parts of speech in spoken registers with parts of speech in written registers in a corpus of Swedish).

The spoken language in the corpus comprises about 25 different registers and the written registers are made up of novels (fiction) and newspaper texts (see Allwood, Björnberg, Grönqvist, Ahlsén, & Ottesjö, 2000). As we can see, nouns are the most common part of speech in written registers, while the most common part of speech in spoken registers is pronouns. The difference can partly be explained by the fact that speaker and listener have more shared information available in spoken registers and, thus, do not need to give as many explicit descriptions of what is being referred to. Verbs are the second most common part of speech in both spoken and written registers. This is probably explained by the central role of the verb for predication, which, of course, is central to both spoken and written registers. As we can see, verbs have a slightly higher relative share in spoken registers, which can perhaps be explained by the higher incidence of information packaged in nominalized form in written registers (see also Biber et al., 1998; Biber, 2006).

Table 1 The parts of speech in spoken and written registers in Swedish (based on the Gothenburg Spoken Language Corpus [GSLC])

<i>Rank: spoken registers</i>	<i>Parts of speech</i>	<i>Share in corpus (%)</i>	<i>Rank: written registers</i>	<i>Parts of speech</i>	<i>Share in corpus (%)</i>
1	pronoun	22.58	1	noun	26.64
2	verb	19.39	2	verb	17.03
3	adverb	16.30	3	pronoun	16.45
4	noun	12.24	4	preposition	11.40
5	conjunction	8.41	5	adverb	9.78
6	preposition	7.14	6	adjective	7.52
7	feedback	5.96	7	conjunction	7.38
8	adjective	4.12	8	numeral	3.36
9	own communication management	2.18	9	feedback	0.27
10	numeral	1.51	10	interjection	0.16
11	interjection	0.18	11	own communication management	0.00

Adverbs and conjunctions are more common in spoken registers, while adjectives and prepositions are more common in written registers. Part of the explanation for this is that spoken registers have more main clauses linked by conjunctions, while written registers use more adjectives as modifiers in complex noun phrases and prepositions to build complex prepositional phrases, where more or less relevant circumstantial information is given.

Feedback words (fb words, e.g., *yes*, *no*, *m*) and “own communication management” words (ocm words, e.g., *eh*, *m*), used for hesitation, planning, and turn-keeping, are very much more common in spoken registers. This is not surprising, since their primary function lies in structuring spoken-language interaction and they really only become relevant in written registers when authors are trying to recreate dialogue.

There are also investigations of grammatical variation between written registers or between spoken registers. Some very interesting examples of variation between written registers can be found in Biber et al. (1998, p. 60), where it is shown that nominalizations are almost four times more common in academic prose (44,000 per million words) than in fiction (11,200 per million words), which, among other things, points to the important role of abstract nominal reifications in academic prose. Another observation pointing in the same direction is that the noun–verb ratio is almost twice as high in academic prose compared to fiction. In both these cases (nominalizations and noun–verb ratio), fiction is closer to spoken conversation.

When it comes to clause types, Biber et al. point out that *that*-clauses are more common in conversation than in academic prose and both extraposed *that*-clauses and *to*-clauses are more common in academic prose than in conversation.

There are also some interesting observations on tense variation in the verb phrase (Biber, 2006, p. 61). Most academic prose avoids the past tense (overall, less than 20% of all verbs are in the past tense). However, the dispreference is greater in some disciplines than others.

Engineering textbooks have only 5% of all verb phrases in the past, while education textbooks have 30% and humanities have 40% in the past. The explanation might be that engineering tries to give a timeless impression of what is being described, while this is less so in the humanities and social sciences. The texts from education use the past tense to report on past studies and past experiences in the classroom, while the humanities often provide descriptions of development with specific dates.

Relations Between Oral Language and Literacy

ANNE HAAS DYSON

One might expect oral and written language to be perceived as having an intimate relationship, born of their kinship as modes of verbal communication. Quite the opposite is the case: one mode or the other has reigned supreme. This contentious relationship is not just a matter of scholarly interest. Ultimately, views of this relationship have consequences for the formal education of children and youth.

Ancient traditions of linguistics were influenced by prestigious religious and legal texts; the languages of those texts had to be preserved and, thus, their rules analyzed and taught as spoken languages changed (McGregor, 2009). In contrast, modern linguists of the early 20th century valued speech as the key source for understanding a language's grammatical system; they stressed a language's common features, not those that may have distinguished great writers (e.g., Bloomfield, 1933). By the 1970s, though, the relationship between oral and written language was itself a matter of intense scholarly attention. The two language modes were pitted directly against each other. On one side of the dichotomy was oral language, seen as a defining characteristic of being human and a pervasive medium of everyday interaction. On the other side was the relatively recent challenger, written language, seen as a tool for advancing individual and societal memory and reason and, thus, a defining characteristic of the "developed" world.

In recent decades, written and oral modes have begun to reconcile, as their battle for superiority has waned. They have been portrayed as situated symbol systems; they have both shared and differentiated potential as resources for representing and exchanging meanings. Ultimately, they find their niche in a social group's communicative repertoire, their respective uses adapted to the cultural, economic, and technological circumstances of people's daily lives. Indeed, in popular literacy practices, like spoken-word performances, and in ever-evolving digital media practices, speech, writing, image, and music are interwoven in multimodal productions.

The following sections consider the visions of oral and written relations that have dominated for the last 50 years, as well as how those visions have been complicated by popular culture and new technologies and, further, how they mediate issues of identity and power. The final section of the entry focuses on the ways in which different views of oral/written relations have influenced pedagogical visions of children's resources for, and means of, learning written language and, moreover, of the goals guiding language arts curricula themselves.

A Dichotomous Relationship: Maximally Different Modes of Language

Six-year-old Ezekial wanted to write "loud" that it would be cool playing soccer with his friend Jason. He wrote

2 RELATIONS BETWEEN ORAL LANGUAGE AND LITERACY

.C.O.O.L. P.L.A.I.N.G.

- Why did you put all the periods?≡ I asked.
- Because I want all of >em capitalized,≡ he explained (i.e., he was following the rule that a capital letter comes after a period).

In the above vignette (from Dyson, 2008), Ezekial was grappling with certain material affordances of oral and written modes. Written language is a second-order symbol system; that is, it is “a system of signs that designate the sounds and words of spoken language, which, in turn, are signs for real entities” (Vygotsky, 1978, p. 106). However, writing is not simply transcribed speech. For example, alphabetic signs, or letters, are selective in the aspects of the phonological or sound system that they represent (Sebba, 2007). Moreover, they do not systematically capture the sensual qualities of speech. Ezekial, though, tries to do so. Like a novelist or cartoonist aiming to capture the sound of a voice, he uses capital letters to indicate volume. Yet, even as he shouts out his pleasure, Ezekial attends to the standard punctuation rule for written prose—a capital letter follows a period (which conventionally indicates a syntactic unit, a sentence).

In the dichotomous view of oral/written relations, written language’s intellectual and societal power is seen as in fact deriving from its removal from the sensual qualities of speech (intonation, stress, volume) and, also, from face-to-face encounters. Anthropologists (e.g., Goody & Watt, 1963) and psychologists (e.g., Olson, 1977) stressed this “autonomous” quality of written language; they put forward arguments about its consequences for both societal evolution and human cognition. These theorists articulated a “great divide” between literate and oral societies and between literate and illiterate individuals.

Against the backdrop of oral traditions for organizing and disseminating knowledge, written language, with its graphic dimension, lent itself to new ways through which societies could store, organize, and pass on information. Further, the alphabetic system was seen as amenable to the explicit representation of meaning in written texts; it thus supports the logical analysis of written statements themselves, separate from contextual common sense. Linguists in synch with this view focused primarily on quintessential oral and written texts (i.e., oral conversation and expository prose); they portrayed the two channels of verbal communication as maximally different registers of the language. For example, Chafe (1982) illustrated that, compared to oral conversation, written expository prose is produced more slowly and, given its material tracings, lends itself to reflection and revision. Thus, relative to conversational talk, expository written prose is more syntactically complex and compact, its ideas more elaborated (i.e., less embedded in an ongoing physical context).

Categorical boxes tend to deconstruct as their contents become unruly, and this is what happened to the dichotomous categories of oral and written language. Cultural anthropologists documented metalinguistic and analytic reasoning in the oral discourse practices of societies without written traditions (e.g., Finnegan, 1988). Sociolinguists noted the ways in which seemingly “oral” performative features, like rhythmic repetition and metaphoric expression, characterized celebrated achievements in written literature. Most dramatically, social historians and ethnographers of communication retheorized the nature of the relationship between oral and written language: it depended, not on the autonomous properties of a communication channel, but on the situated nature of its use.

Dynamic Relationships: Situated Modes in Communicative Use

Social historians undermined the dichotomy of oral and written language by painstakingly documenting the literacy “myth” (Graff, 1987). Just as there was no sudden arrival of oral

language, so too there was no abrupt arrival of written language and, moreover, no clean separation between the two modes. Written language spread gradually, its nature and use reciprocally related to the oral world in which it took shape. Further, there were no consistent societal consequences following the spread of an autonomous literacy: written language could be withheld from the masses or particular groups of people; it could be used to issue edicts and orders to control and limit behavior; and the elites might employ it to develop their economic plans, even as their workers had no use for it. Written language is thus "ideological," infused with the cultural, political, and economic dynamics of the institutions in which it is embedded (Street, 1984).

There are also no consistent intellectual benefits to learning written language. The cultural psychologists Scribner and Cole (1981), in a study of the Vai people in Liberia, illustrated that the cognitive benefits of written language depended on the nature of the goal-directed activity in which it was learned and used (i.e., the literacy practice); using literacy for a practice involving rote memory, as in particular religious training, yielded different benefits than one involving communication to a distant audience, like letter writing.

Scribner and Cole's work, linked to that of ethnographers of communication, gave rise to the notion of multiple literacy practices, with varied potential consequences. Both written and oral language are part of the communicative repertoire of particular social groups. Variations in that repertoire reflect individuals' participation in those groups, which are themselves sites of intersecting economic, political, and cultural forces like immigration, recession, and technological change.

Further, within any practice, oral and written language may be woven together in complex configurations as people gather to produce, use, and talk about texts for some purpose. For example, in the southern African American neighborhood studied by Heath (1983), written texts, be they newspapers or government forms, were typically reshaped in oral discourse, as people talked about their meanings; similarly, in church, the written word was lifted from the page as the preacher elaborated that word into an oral performance that enveloped and involved parishioners. In her study of the oral and written repertoire of urban junior-high students, Shuman (1986) argued that the adolescents' social lives were enacted through texts whose nature could not be simplistically categorized as oral or written. For example, a diary entry was similar to a conversational narrative in substance and style, but quite different in its social enactment: conversational narratives had relational consequences that private diary writing did not. Still some collaboratively written texts, shaped by peer talk and directed to adult authorities, were meant to have social consequences.

Sociocultural studies concerned with literacy development have illustrated how young children are socialized into communicative practices by observing, participating in, and playfully reenacting the talk-filled communicative events of families, communities, popular media, and formal classrooms (Razfar & Gutierrez, 2003). Because they hear, not just see, enacted literacy practices, they are able to "read" and playfully compose written texts well before they grasp the conventions of the symbol system.

This situated view of oral and written relations has thus provided vivid illustrations of the interwoven nature of oral and written resources in the contexts of particular lives. Informal interactions, collaborative work sessions, and formal meetings are all occasions for the generation, development, presentation, and revision of ideas encoded in diverse media, including print, and they are also occasions that generate, sustain, and enact relationships. Indeed, in contemporary times, oral and written languages may combine with music and images for complex multimodal and, indeed, multilingual productions; with the support of new digital technologies, those productions mediate local and global relations.

Designed Relationships: Spoken Word and Other Multimodal Productions

As language modes became part of a complex of semiotic resources for the production of texts, the term *design* was proposed as more descriptive of the process of making multimodal texts than *composition* (New London Group, 1996). Within a particular multimodal practice, different semiotic materials, including speech and writing, have different semiotic affordances, that is, their properties lend themselves to representing different kinds of meaning. Any resulting text is not a collage but a dynamic whole, as the modes complement or complicate each other. In a digital story, for example, music's rhythm may contextualize a narrative line of speech, itself punctuated by visual displays and iconic key words (perhaps even *COOL*); all work together to construct a multilayered meaning (Hull & Nelson, 2005).

Multimodality is not new. For example, young children's early writing has been described as "symbol weaving" (Dyson, 2001): written language may be one strand of a drawn, spoken, played out, and even sung world. The increasing importance of popular media in children's lives has underscored how talk, images, props, and written text may be interwoven in their play with well-known characters and plot lines. From a design perspective, children's developmental challenge is to learn the particular affordances of differing media in different communicative circumstances.

To further illustrate, poetry has long been linked to the human voice and to communal gatherings, even though its written form may cloud its ancient oral roots: it is "composed by the ear . . . designed to be heard" (Collins, 2003, p. 4). In contemporary times, spoken-word artists may wrestle with the poetics of their written words, but their writing is designed for oral performance, for the infusion of the flexible aesthetics of the human voice, and may include the accompaniment of music, dance, and other nonverbal modes. Spoken-word artists, linked to the cultural movement called hip-hop and, particularly, to rap, are rooted in meanings found and voices heard on city streets. With digital technology and, particularly, the Internet, locally grounded spoken-word performances travel globally and are appropriated and refashioned by youth wielding writing tools and flexible voices across cultures and languages.

Aesthetic texts, be they described as "spoken word" or "written novel," are prime textual sites for representing the voices—and the many spoken languages and language variants—found in culturally complex societies, where national borders and cultural ones are routinely crossed. In the intricate relationship of spoken and written symbols may be found complex issues of identity and politics.

Identity, Power, and Oral/Written Relations

In any language, vernaculars or spoken variants index sociocultural, historical, and geographic complexities. For example, variations in pronunciation, vocabulary, syntax, or discursive practices (e.g., greeting, storytelling, preaching) may index regional roots, ethnic cultures, and social classes. Given this backdrop of societal heteroglossia (Bakhtin, 1981), that is, of the complexity of a society's language(s), the relationship between oral and written language becomes a site for issues of power and identity. These issues flow from a central observation: The language of the politically and socially dominant group is regarded as the idealized "standard" (Milroy & Milroy, 1991). It is typically represented in, and influenced by, the standardized written system and its orthography, and its use is monitored and taught by the schools.

Spelling is a particularly illustrative site for the display of identity and political work around oral/written relations (Sebba, 2007). Conventional spelling can be manipulated to convey a vernacular voice, and doing so may serve or challenge the status quo. On the one hand, authors' deliberate respelling of words to convey perceived pronunciations, like their use of nonstandard syntax, may index the supposed "uneducated" language of particular social groups (Preston, 1985). On the other hand, such actions may be a powerful community means of self-representation and identity construction. For example, Olivio (2001) analyzes written rap lyrics for those orthographic and syntactic choices that speak to African American Vernacular English (AAVE). Among represented features are the absence of [r], the voiced stop for [th] (e.g., *dey*), and zero copula (e.g., *What side you on?* [p. 76]). The use of apostrophes suggests the deliberate manipulation of, and resistance to, dominant conventions (e.g., *po'* for *poor*).

Youth practices may entail an effort to craft vernaculars into written aspects of multimodal texts on diverse surfaces, among them T-shirts, backpacks, electronic spaces, concrete walls, and even bodies. For example, a young woman constructed herself as a "True Hamoz [true Samoan]" on her backpack; this, she wrote, was a commitment "fo lyph," an AAVE-inspired spelling (Paris, 2010). Identity is manipulated and even played with through electronic media, where language-learning youth may find communicative spaces for constructing multilingual selves and trying on written versions of vernaculars, safe from the evaluations of both teachers and peers (Lam, 2009).

This manipulation of written language to capture oral language differs from young children's invention of spellings based on their spoken words. Their writing may be influenced by home vernaculars, but it is unlikely to be a deliberate rejection of dominant conventions. Nonetheless, children, like literary artists, do violate known conventions to capture graphically the sensual qualities of the human voice. Although they tend to find syntax-based conventions difficult, children, like Ezekial and his peers, may more readily make drawn characters SHOUT, SCREEEEEEEM, and declare "I love you" in pictured dialogue bubbles (Dyson, 2008).

Educational Implications of Oral/Written Relations

Perspectives on oral/written relationships that do not portray these modes as dichotomous but, rather, as intertwined in cultural practices, collaborative partners in designed texts, and resources for crafting expressive selves suggest new visions of formal language-arts curricula and of learners themselves.

Within a dichotomous view, the seeds of school success are sown in the home, as parents read to children and talk to them in particular ways about books and their own experiences (Snow, 1983). Children from backgrounds deemed "non-mainstream"—particularly those without the bedtime storybook ritual—are at risk because they are too "oral," so to speak. This view supports an emphasis on the "basics" of literacy education (letters and sounds) and on explicit "literate" language lessons for low-income children.

To learn the use of any symbolic tool, learners need relevant experiences from which they can appropriate as they approach new demands. More situated views of oral/written relationships have led to broader visions of the communicative practices that may offer pathways to school literacy (e.g., cultural discourse practices, like oral storytelling, and media-based play, like assuming character identities). Such pathways are enveloped in talk among students, peers, and teachers. Through talk, others involve learners in the social use of literacy, modeling and guiding the necessary processes and responding to their efforts in situationally appropriate ways (Vygotsky, 1978). Students' production of even

the most formal of academic essays depends, not just on learning the characteristics of a text type, but on connecting new textual demands with related social practices and with the disciplinary conversations they are joining.

Finally, the fluidity of human populations, languages, and multimodal texts suggest new basics and goals for language arts education. These take into consideration children and youth's alertness to the communicative repertoire and symbolic material of their everyday lives. These basics would involve differentiating and expanding one's semiotic resources (e.g., symbol systems, languages, genres, spelling manipulations, punctuation possibilities). The goal would be, not the singular mastery of a standardized written language, but communicative flexibility and critical reflection, which would underlie thoughtful, playful, and public participation in an ever-changing world.

Reliability in Language Assessment

CAROL A. CHAPELLE

Almost any test user will readily agree that tests should be valid and reliable, but if asked to explain what “reliability” means, most test users would be hard pressed, despite the widespread use of this measure in the documentation that accompanies language tests. Assessment experts would also agree that reliability is a central concern for interpreting assessment results, even to the point that it is an important part of most validity arguments. However, the experts would also point out that reliability is not a characteristic of a test, but rather a characteristic of test scores obtained from a given test administration or administrations.

Reliability, which means *consistency* or *stability* in language assessment, is most simply explained with reference to classical test theory, which posits a true score that an examinee would obtain on a test that was a perfectly reliable measure of an attribute. Such reliable tests exist only in theory but, hypothetically, if the attribute of interest were assessed by gathering many samples of performance on many tests of the attribute, a close approximation of the true score could be made. As Haertel explains,

Any of these possible scores would have served the purpose of measurement equally well, but they would not all be identical. Taken together, this hypothetical collection of scores represents the general, enduring attribute of interest. Thus, it is important to determine the extent to which any single result of the measurement procedure is likely to depart from the average score over many replications. Other things being equal, the greater uncertainty associated with the results of the measurement, the less confidence should be placed in that measurement. (Haertel, 2006, p. 65)

The assumption underlying this perspective is that sources of inconsistency in test scores produce measurement error in the test scores. This error can come from factors such as difficult conditions for listening during a listening test, fatigue on the part of examinees, unclear instructions in one section of a test, poorly written test tasks, inadequate scoring rubrics on a writing test, or simply an inadequate sample of performance. The assumption is that any of these conditions arising from test development, test administration, and test scoring will affect scores randomly whereas performance based on the defined attribute (e.g., language ability, listening comprehension, vocabulary knowledge) will affect scores consistently. Estimating reliability, then, becomes a matter of sorting out the amount of consistency in scores from the amount of error.

Estimating Reliability

Methods for estimating reliability within a classical test theory perspective depend on the sources of error that one wishes to isolate, but each method is based on the fundamental idea of replication that Haertel described. Brennan (2001) argues that “the notion of replications is central to an understanding of reliability” because “reliability is a measure of the degree of consistency in examinee scores over replications of a measurement procedure”

(pp. 295–6). In order to understand the reliability of any particular measure, then, the test developer needs to be able to define what a replication of the test in question would consist of. The clearest type of replication in testing is two administrations of the same test. A reliability coefficient is calculated as the correlation between the two sets of scores obtained by examinees who took the test twice, and such a reliability estimate is called the test–retest reliability. Parallel-forms methods require two forms of a test to be administered to the same examinees so the consistency of performance across forms can be estimated. In both cases the statistical procedure for estimating reliability is a correlation between the two sets of scores. Despite the methodological clarity of test–retest (and parallel-forms) reliability, in operational testing programs it is difficult to obtain two sets of test scores on exactly the same test or a parallel one from the same group of examinees. Instead, a variation of a split-half method is used in many operational settings.

Split-half methods treat a half of a test as a replication of the other half, and are therefore also called internal consistency reliability methods. Cronbach’s alpha is the most widely used of the many methods for estimating internal consistency reliability in language testing and elsewhere. It can be calculated through the use of SPSS, for example, when the researcher has the item scores (dichotomous or polytomous) for each test taker. Inter-rater methods assess the consistency between the ratings given by two or more raters to a set of test performances, typically using a correlation. Observed reliabilities are affected by the manner in which the reliability was estimated. When the two testing events are separated by time, as in test–retest coefficients, they tend to be lower than when all samples of performance are obtained in a single testing event (Gronlund, 1985).

In each of these cases a statistic estimating the degree of relationship, or consistency across the repetitions, is used to indicate the reliability of the test scores. It is expressed as a value that can range from 0, meaning variation in test scores is completely random, to 1, indicating that variation is completely reliable, that is, attributable to one factor. Reliabilities of .90 and higher are considered very good, whereas reliabilities of below .70 indicate scores containing a lot of error. Whether or not the amount of error is too great, of course, depends on the nature of the test and its use. For a high-stakes test such as the Internet-based Test of English as a Foreign Language (TOEFL iBT®), which is used for admission decisions, an internal consistency reliability of .94 is reported for total scores (Enright & Tyson, 2011). However, this test takes hours to administer and contains multiple sections with multiple test tasks. Shorter tests with fewer items typically do not produce scores with such high reliability estimates. Such tests may still be entirely appropriate and useful for their intended purposes.

Applied linguists can find a discussion of reliability and instructions for calculating reliability in any current introductions to language testing, but Bachman (2004) and Brown (2005) provide the most thorough treatment. However, applied linguists tend to be interested not only in calculating reliability but also in interpreting it. They are therefore interested in understanding how observation of consistent performance can accurately reflect an attribute such as language ability that has so many inherent inconsistencies.

Should Language Performance Be Consistent?

Books on language assessment that present an in-depth perspective on the construct of language ability (Bachman, 1990; McNamara, 1996) hint at a potential contradiction between the way the construct is defined and the expectation that a good measure will exhibit consistencies in performance. Bachman’s presentation of the multifaceted communicative language ability posits multiple factors including knowledge of aspects of language (e.g.,

vocabulary, pragmatics), strategic competence, and topical knowledge as part of the construct. If the construct of communicative language ability is itself so multifaceted and variable across language use contexts, why do language testers hold reliability up as an ideal quality in test performance?

In recognition of this apparent contradiction, Swain (1993) questioned the relevance of internal consistency reliability for test scores which are intended to reflect examinees' communicative language proficiency. If the construct of communicative language proficiency would not itself be expected to be internally consistent because it consists of components that do not necessarily develop simultaneously, how can consistency in test performance across tasks, occasions, or forms be sought? The consistency of measurement versus variability of construct meaning is a theme that is taken up regularly in applied linguistics, where many teachers and researchers see the variability of language ability as more evident and pertinent than the consistency, and thus question the utility of language tests, whose *raison d'être* is to provide scores that offer a consistent summary of examinees' language ability.

One approach to reliability taken by Bachman and Palmer (1996) is to recognize that the way the construct is defined will affect the expected level of reliability in scores. "If the construct definition focuses narrowly on components of language ability, the test developer can reasonably expect to achieve higher levels of reliability than if the construct is complex, including a wide range of components of language ability, as well as topical knowledge" (p. 135). Therefore in determining an acceptable degree of unreliability for a test, rather than categorically seeking maximum consistency, test developers are to analyze their tests to make sure that they do not produce scores reflecting unmotivated inconsistency. The idea that reliability needs to be evaluated in view of the construct definition and its degree of expected variability is useful in both practice and research.

Another useful perspective comes from Snow and Lohman (1989), who distinguished between the type of psychological model containing many components and processes that underlie performance and the psychometric model that is constructed to capture response consistencies. Mislevy (2006) takes this farther by displaying graphically the different levels of models that applied linguists may work with, from the delicately defined linguistic knowledge and processes, to a rougher construct description representing some of the primary components, to a psychometric model which can be expressed mathematically. Mislevy's approach emphasizes that assessments use models in order to capture a view of the attribute that is useful for some purpose. In this sense all models are inaccurate because they fail to capture some of the detail of the attribute; however, the criterion for the success of the model is not its correctness, but its usefulness. What is needed is models that are not so wrong as to not be useful, and for most purposes models underlying tests need to be consistent.

In contrast to these construct-relevance perspectives to reliability is another argument about the exclusive definition of reliability as replication. Moss (1994) notes that for many types of high-stakes decisions such as selecting manuscripts to appear in journals and applicants for academic jobs, the manner in which quality decisions are made does not draw upon the assumption that evaluators serve as replications. Instead, she argues that quality ratings are obtained by engaging in a hermeneutic process of expert judgment where experts apply their own judgments to arrive at an evaluation which may or may not agree with that of the whole group. Moss questions the unconditional value placed on reliability-as-replication as an indicator of test quality within validity arguments. She would rather "consider it one alternative for serving important epistemological and ethical purposes—an alternative that should always be justified in critical dialogue and in confrontation with other possible means of warranting knowledge claims" (Moss, 1994, p. 10).

Using Reliability Estimates

Reliability estimates are used regularly in the everyday business of language testing and in research that uses language test scores as one source of data. These uses of reliability attest to its utility in helping test users interpret individual test scores and the performance of a set of test scores in research. Reliability is fundamental to understanding the precision of individual test scores as indicators of an attribute because it is used to calculate the standard error of measurement, a metric directly interpretable as a range of test scores relative to the observed score where the examinee's true score probably lies. For example, the reliability of the TOEFL iBT noted above is placed into a formula to return a value of 5.64 as the standard error of measurement. This means that an individual who obtains a score on the TOEFL iBT can be assumed to have a true score within ± 5.64 of that score, with 68% probability. If the reliability of the TOEFL iBT scores were lower (i.e., less precise) the standard error of measurement would be greater, meaning that for any observed score, the true score would be within a larger range. The standard error of measurement is also useful for reminding test users that examinees' test scores (i.e., their observed scores) are only an approximation of the scores that the examinees would obtain based on their abilities if they were to take the test repeatedly so as to obtain a more accurate estimate of their ability. This theoretical score is called the true score, and it is something that can only be estimated, not known.

In research, reliability provides an indication of the extent to which scores obtained on a measure actually reflect one construct, in other words the extent of the true score ability that is the source of variation in scores. This is important because if a researcher is claiming to use a test score to mean one construct, such as grammatical knowledge, speaking ability, or communicative competence, and the score is intended to distinguish among test takers on the basis of their level of one construct, reliability evidence is needed. Moreover, statistically, the reliability of the measures in research affects the performance of the scores in other statistical procedures in correlational and experimental research. Both types of research seek to find systematic differences among test takers, but cannot do so unless the measures produce scores that distinguish consistently among test takers.

Because reliable test scores are most useful, one of the chief goals of test development and administration is to maximize reliability by assuring systematicity in all aspects of test development and administration. The chief rule of thumb is that the more samples of performance (i.e., the more test tasks) the more reliable the test scores. This rule follows from the basic definition of reliability as consistency across repetitions. Second, test developers attempt to minimize error associated with confusion about test tasks by trialing test items using just a few test takers to make sure tasks are clear. They also pretest items on a sample that is similar to the intended test takers because it is the set of test scores for which reliability is estimated rather than the test itself. This means that a test that produces reliable scores for one group of students may not for a second group with different characteristics. It is worth repeating that reliability is not a characteristic of a test, but a characteristic of a set of scores. Test developers also conduct analyses of the items to identify those that do not contribute to the reliability of the measure.

Limitations of the Classical Test Theory Perspectives

The fundamental concepts about consistency of test scores can be expressed from a classical test theory perspective, but today other approaches are used as well. Item response theory (Lord, 1980) provides item-level information about reliability that is useful for test development, particularly development of computer-adaptive testing. Generalizability theory

offers a means of isolating within one model components of error associated with different sources (Bachman, 2004). Structural equation modeling (Kline, 2005) tests the reliability of a measurement model within a more complex structural model. In all of these approaches, the language test is intended to capture what is consistent in the variation among a group for norm-referenced interpretations.

In classroom tests, such as a final exam, however, tests are intended for criterion-referenced interpretations and therefore the assumption that the desirable set of test scores should spread examinees across a normal distribution does not hold. In classroom tests, test takers' performance should be evaluated against a criterion of how much knowledge, skill, or understanding they displayed on the test. There remains an issue of consistency, however, because one would want examinees' scores to be consistent if they took the test twice or if different questions were used to elicit the performance concerning a particular ability. When criterion-referenced tests are used, consistency is estimated through the use of a metric of dependability (Brown & Hudson, 2002).

Despite the variety of approaches taken to reliability in different situations today, the basic concepts about reliability from a classical test theory perspective remain important for understanding the fundamental idea of what consistency means and why it is important.

Religion

SOHAIL KARMANI

Of all the manifestations of human culture, language and religion are by far two of the most striking and most enduring—so much so that they are likely to feature very prominently as markers of group cultural identity, and in so doing inform our basic ideas as to how we set about defining and ordering the world. It is not surprising then that the history of civilizations is punctuated with conflicts that would appear to arise along mainly linguistic and religious lines. This is not in any way to suggest that language and religion are per se sources of conflict, rather that they lend themselves as easy pretexts (when or if a political or ideological need arises) in public appeals for reinforcement of the “home” culture and, in many instances, systematic vilification of the “enemy.”

It is worth noting for instance that the term “barbarian” was first coined by the ancient Greeks during the Greco-Persian wars (499–449 BC) as a term of abuse in reference to the speech of the Persians. As the ancient Greeks then saw it, the Persians “babbled” in a language that was neither Hellenic nor one of the several Greek dialects—hence the onomatopoeic origin of the Greek term “barbaros.” Much less surprisingly, the use (or more fittingly the abuse) of religion also played a key role in that conflict in further polarizing the two sides with each invoking their respective deities.

As regards the modern European era, particularly since the Peace of Westphalia (in 1648), the role of language and religion has been hugely significant in fostering the emergence and survival of the nation-state as we know it today. Specifically, the process of institutionalization has been crucial in conferring legitimacy to the idea of the official language(s) and religion(s) of the state. Interestingly, as Safran (2008, p. 172) observes, it has been largely through the process of institutionalization that a dialect is effectively raised to the status of official language and in much the same way a belief system is accorded the role of “state religion.” It is not difficult then to appreciate how taken together language and religion have often served as the primary conduit through which disparate ethnic peoples could be homogenized and through which—often with considerable savagery—the nation-state has sought to establish a cultural consensus on which its legitimacy could be founded. Remarking on the instrumental role of language and religion in the management of state affairs, Immanuel Kant (1724–1804), the 18th-century German philosopher, wrote:

It is . . . the desire of every state (or its ruler) to achieve lasting peace by . . . dominating the whole world, if at all possible. But *nature* wills it otherwise, and uses two means to separate the nations and prevent them from intermingling—*linguistic* and *religious* differences. These may certainly occasion mutual hatred and provide pretexts for war, but as culture grows and men gradually move towards greater agreement over their principles, they lead to mutual understanding and peace. (Cited in Reiss, 1991, p. 113; original emphasis)

Indeed, over time, with varying degrees of success, the nation-states of Europe were able to impose a political geography on the European landmass that was largely ordered along mainly linguistic and religious lines. At the domestic level, this process of cultural consolidation was given a further boost with the dawning of the industrial revolution and

the subsequent urbanization of Europe's major cities. It was notably during this period—with the radical shift in the demography of the nation-state—that state-sponsored mass education systems as we know them today took root and began to take shape. Among other things, these nascent educational systems were to play a crucial role in molding the incoming rural masses and as a consequence help in further entrenching the official roles of language and religion.

But more broadly, at the international level, there was also a new dynamic that coincided with the industrialization of Western Europe. The steadily growing competition between rival nation-states for distant markets and resources—primarily in Africa, Asia, and the Far East—effectively ushered in the age of empires. And once again, to support this expansionist phase in development of the nation-state, language and religion frequently served as highly effective pretexts for plundering distant lands and subjugating foreign peoples. Indeed, as the case for empire was often framed, it was deemed the moral duty of the expansionist nation-states of Europe to “civilize the natives” and in so doing deliver them from their perceived backwardness and generally “pitiful” state of existence. Not infrequently, this self-styled “civilizing” mission took on a religious and linguistic dimension prompting rather bold and extraordinary pronouncements about the cultural superiority of European languages and religions. Not untypical of the times were the views of Read (1847) for whom the English language was deemed the “language of the arts and sciences . . . of civilization and religious liberty . . . the store house of the varied knowledge which brings a nation within the pale of civilization and Christianity.” It was against this backdrop of imperial expansionism and a rising tide of European chauvinism that Christian missionary groups were able to better position themselves and thereby pursue their more specific goal of spreading the Gospel to the natives. It bears stressing here that this was sought not simply by spreading the English language and imparting Christian teachings, but also by a painstaking process of studying, documenting, and translating local languages with a view to aiding in proselytization efforts and ultimately of course in making the Bible accessible to subject peoples. In many respects, the Summer Institute of Linguistics, a contemporary US-based organization, can be seen as continuing in the long-standing tradition of translating the Bible into minority languages, as also its sister organization, Wycliffe Bible Translators, whose stated mission is “serving with language communities worldwide to express God’s love through Scripture translation and compassionate service.”

Gradually, however, as the age of empires began to wind down, subject populations found themselves coming to terms with the prospect of independence—a process that often entailed a robust rejection of Western imperialism, but curiously at the same time an eagerness to embrace an ideology of Western nationalism and with it a post-Westphalian blueprint for a nation-state. Eventually, what emerged of course (as we know it today) was a global system of nation-states, two particularly striking examples being Israel and Pakistan, both of which were founded explicitly on the basis of language and religion.

It could be argued—and perhaps with some merit—that the history of the relationship between the nation-state on the one hand and language and religion on the other has to some extent proved beneficial in promoting social cohesion, national harmony, and a deeply imbibed sense of citizenship. Undeniably, on several levels, current-day nation-states that share common bonds of language and religion are more likely to display a stronger sense of cultural, economic, and political proximity. The international ties that, for instance, link the English-speaking nations of the West have arguably a lot to do with their common linguistic and religious roots in much the same way as the common cultural heritage of the Arab League nations is to a large extent rooted in their collective experience of Arabic and Islam. Even so, it would be grossly disingenuous here not to point out that the nexus between the nation-state, language, and religion has also in many instances proved to be hugely catastrophic for linguistic and religious minorities, often leading to

untold misery and destruction for millions. Several modern-day examples come to mind; particularly worth mentioning here is the partitioning of British India (in 1947) during which several communal groups that had otherwise coexisted for centuries in relative peace were eventually torn apart by appeals to religious differences to be later abetted by artificially manufactured linguistic differences between Urdu and Hindi.

In more recent times, particularly since the end of the Cold War, language and religion have emerged once again as potent forces on the international stage. In 1992, Samuel Huntington (1927–2008), a renowned American political scientist, formulated his much-celebrated theory of the clash of civilizations. In a seminal 1993 article, Huntington proposed that the primary source of conflict in the post–Cold War world would be rooted in cultural, religious, and linguistic differences. Of particular concern to Huntington was what he saw as the intensifying civilizational clash between the West and the Muslim world. The controversial theory, though dismissed by a wide variety of critics at the time, rose to prominence in the aftermath of the terrorist attacks of the September 11, 2001, effectively becoming a convenient theoretical model for explaining subsequent global events in the greater Middle East region. One notable site wherein the intersection between language, religion, and politics has attracted the attention of geopolitical policy makers is in the ascending role of English-language teaching as a “public diplomacy” vehicle for pursuing narrow ideological goals of US power in the Arab and Muslim world (see, e.g., Karmani, 2005a, 2005b, 2005c, 2006).

Research Articles in English for Specific Purposes

DWIGHT ATKINSON

The research article (RA) is the single most analyzed genre in English for specific purposes (ESP). This is understandable—it has been the main outlet for new knowledge in natural science and medicine for the past 150 years, and, in the 20th century, engineering and social science.

Defining the RA

Many RA studies assume a common definition: journal articles in empirically driven research fields reporting original research, with the experimental RA as primary exemplar. A further defining feature for some is the Introduction–Methods–Results–Discussion (IMRD) discourse structure. But the father of ESP RA studies, John Swales (2004), has argued that this definition is inadequate: RAs appear in marginally empirical fields like computer-simulation-based engineering, and nonempirical ones like theoretical physics; they may furthermore include review articles, natural history papers, and other work departing from assumed norms. For present purposes, I adopt the more commonly assumed definition—but as a *prototype* definition and without IMRD as a defining criterion.

History of the RA

The RA's history began with the founding of the first scientific journals. Foremost among these was the *Philosophical Transactions of the Royal Society of London (PTRS)*, established in 1665 and published almost continuously since. According to Atkinson (1999), papers in the early *PTRS* were usually author-centered, epistolary, brief, and somewhat miscellaneous in form and content. Where featured at all, experimental methods and results were relatively unelaborated, but became more elaborated by 1775. By 1825, articles were longer, research was being embedded in specific research communities, and the author-centered rhetoric was being replaced by an object-centered one. By the mid-20th century, papers showed much less concern for embedding research problems in particular communities, theoretical concerns took precedence, and research methods were commonly de-emphasized.

Various cross-time studies of scientific and medical RAs have been conducted. Each varies according to the texts sampled and analytic methods employed, but their findings tend to reinforce one another (Swales, 2004).

Present-Day RAs

Rhetorical Moves in RAs

The most analyzed aspect of present-day RAs has been their introduction sections. This is due predominantly to Swales's influence—his earlier work (e.g., 1990) focused on RA introductions, and was expanded in later publications (e.g., 2004). Along the way, Swales

The Encyclopedia of Applied Linguistics, Edited by Carol A. Chapelle.

© 2013 Blackwell Publishing Ltd. Published 2013 by Blackwell Publishing Ltd.

DOI: 10.1002/9781405198431.wbeal1005

developed not just a description of, but a methodology for, studying RAs: *rhetorical move analysis*.

A “move” is a functional rhetorical unit within a larger, more-or-less ordered sequence. Swales’s (1990) widely used “create a research space” (CARS) model divides RA introductions into three basic moves, originally labeled: “establishing a territory,” “establishing a niche,” and “occupying the niche,” with each move encompassing a series of “steps,” or submoves. Swales (2004) revised the CARS model in various ways, including renaming the third move “presenting the present work.”

Many authors have applied Swale’s analysis to their own RA introduction samples, testing its validity and scope. Numerous attempts have also been made to determine move sequences for other RA sections, study move variation in RAs across disciplines, and study move variation in RAs across languages.

Functional Linguistic Features in RAs

A substantial literature examines functional linguistic features in RAs. Hyland (1998), for example, studied the use of *hedges* to qualify truth claims—their major rhetorical function in RAs, where community acceptance is crucial to establishing findings as facts. Examining 27 articles from molecular and cell biology, Hyland developed a “polypragmatic model” of scientific RA hedging—“polypragmatic” because hedges often serve multiple functions simultaneously in RAs. The model includes two major “fuzzy” categories: *content-oriented hedges*, which mitigate differences between authors’ views and field-accepted understandings; and *reader-oriented hedges*, which foreground the author–audience relationship.

Other notable studies of functional linguistic features in RAs include Vande Kopple (1998) on relative clauses, Rodman (1994) on active-voice verbs, Martínéz (2005) on first-person pronouns, and Halliday (1988) on nominalization and grammatical metaphor, although this last study does not concern RAs exclusively. Many other features have also been studied, both singly and in terms of their *probabilities of co-occurrence* (e.g., Atkinson, 1999).

RA Composing and Reading Processes

Composing process research and research on the construction of scientific knowledge combined in the 1980s and 1990s to yield valuable insights regarding the RA. Classic studies include Knorr-Cetina (1981), which revealed the highly constructed, rhetorical nature of RA writing in a food chemistry lab. Myers (1990, chap. 3) tracked two biologists’ experience in getting “atypical” RAs published, centering on complex negotiation of knowledge claims. Berkenkotter and Huckin (1995, chap. 3) studied a biologist responding to journal reviewers’ comments which forced her to emphasize the novelty and larger research context of her claims. In these and other studies, RAs are characterized as highly rhetorical products—strategic arguments more than reports of what actually happened in the lab.

Bazerman (1988, chap. 8) studied research physicists’ RA reading processes, finding that they were selective, nonlinear, and highly purpose-driven. The physicists tended to read papers in their specializations starting with “the news”—title, equations, tables, and graphs of results, moving onto other sections as needed.

Discourse Community Studies

Ethnographies and quasi-ethnographies of academic communities sometimes highlight RA production. Latour and Woolgar’s (1986) ethnography of a Salk Institute for Biological Studies lab concluded that the main purpose of lab activity was to produce RAs—highly rhetorical literate representations of laboratory research, in which knowledge claims were

relentlessly negotiated. Swales (1998) presented a quasi-ethnographic “textography” of three groups of academic text producers—botany researchers, applied linguists, and computer consultants. He found that while RAs were high-value products for two of these groups, other kinds of texts were also produced and valued.

Multilingual Writers and RAs

RA research in the last decade has focused extensively on multilingual writers (MWs) publishing in English. John Flowerdew has been especially active in this area. Surveying 585 Hong Kong academics, Flowerdew (1999a) found that international English-language journals were the favored publication outlet for 85%, and that although two-thirds felt disadvantaged when writing RAs in English, 87% also felt “confident or very confident” doing so, most having received doctorates in English-dominant countries. Flowerdew (1999b) determined that the greatest perceived weaknesses/disadvantages for such writers were facility of expression, vocabulary, time expended, and writing introductions/discussions.

Flowerdew (2000) interviewed 11 applied linguistics/language teaching journal editors on their treatment of MWs’ submissions. All expressed positive concern, many described special efforts to support MWs, and all reported feeling that reviewers treated MWs fairly. They identified MWs’ main writing problems as: (1) addressing research issues in ways relevant to their journal’s readership; (2) establishing research niches in introduction/literature and discussion sections; (3) inadequate authorial voice; and (4) nativized rhetorical styles. Most editors also expressed the belief that MWs enriched the field greatly, offering unique viewpoints, topics, and linguistic sensitivity/knowledge.

Flowerdew and Li (2007) investigated mainland Chinese doctoral students’ reuse of language from preexisting RAs, while Li and Flowerdew (2007) studied the role of professors, language professionals, and peers in helping students get scientific papers published.

Canagarajah (e.g., 2002) described the great challenges in composing English RAs in “off-network” (Swales, 1987) parts of the world, such as his native Sri Lanka. He showed how the Western/Center-based academic publishing system is heavily biased against periphery scholars because the latter have, among other things, virtually no access to current academic literature and little material support (e.g., copying facilities, up-to-date computers, travel funds, or sometimes even paper). Western RA publication is seen as a self-perpetuating process whereby the rich get richer and the poor poorer. A special feature of Canagarajah’s work is that he locates his claims in a specific periphery academic community, and one he is intimately familiar with.

Teaching the RA in English for Specific Purposes

Much of the research reviewed so far was undertaken at least partly for pedagogical purposes. Standard research writing guides present general advice and conventions based on experience but no systematic empirical study of the genre(s) in question. Early pedagogical work in ESP (e.g., Trimble, 1985) took up where such guidebooks left off, basing itself at least partly on actual text analysis, with a focus on functional linguistic and rhetorical features.

The dominant pedagogical approach, however, proceeds from Swales’s work: “genre awareness” or “rhetorical consciousness-raising” (Swales, 1990). A major dynamic in such courses, which often cover multiple research and research-related genres (e.g., conference abstracts, RAs, poster presentations, letters to journal editors), has students learning how their own field’s RAs are structured by collecting text samples and then comparing them with those of their classmates in other fields. Modeling and direct teaching of rhetorical

moves may figure prominently, as does group work, including group composing. More than in other forms of second language instruction, teachers of such courses need to be willing to learn from their students and the research genres of their fields, and to be able to adapt their teaching to students' (at least somewhat unpredictable) needs and situations. Swales and Luebs (2002) described a research writing course for social psychology graduate students where exactly these attributes were paramount. Where students are actually producing texts for publication or evaluation, as in the just-mentioned course, regular one-to-one student-teacher consultations are invaluable.

An ongoing argument in ESP concerns whether subject specialists (e.g., engineers) need to be involved in teaching and developing course materials for genre-specific classes. The current wisdom seems to be that well-informed and experienced ESP teachers (i.e., with large amounts of genre, rhetorical, and linguistic knowledge but no specialist knowledge of their students' fields) can make a substantial contribution to students' understanding of the specialized genre forms and expectations of their field, although some background in a technological/scientific field is a definite advantage. It has also been frequently suggested that teachers assign students "ethnographic" work on research writing in their fields—that is, that they be required to investigate the processes, norms, and expectations of research writing in their specialties.

There are useful textbooks and associated materials for teaching the RA in ESP. Weissberg and Buker's (1990) now-classic *Writing Up Research* combines genre concerns such as move analysis with a focus on functional linguistic features to provide a thorough introduction to experimental RA writing. A second classic textbook, *Academic Writing for Graduate Students* by Swales and Feak (2004a), has a broader purview—only the last two chapters deal explicitly with RAs. Earlier chapters focus on writing skills and text types (e.g., writing summaries and problem-solution texts), which can be regarded as preparatory to RA writing. A teachers' guide for this textbook is also available (Swales & Feak, 2004b).

Conclusion

Empirical analysis (e.g., Baldauf, 2001) suggests that up to 85% of RAs in some fields are published in English, but such figures may actually underestimate English's dominance in RA publication. This dominance has deleterious effects. It advantages so-called native speakers of English and those educated in English-dominant countries, as well as creating conditions in which non-Western-based/English-reported research has little chance of being widely circulated. At the same time, certain advantages may accrue to having a single overarching lingua franca of research, including enhanced ability to share knowledge across (what were formerly, at least) linguistic and cultural borders.

English for Specific Purposes has devoted much effort in the last 30 years to describing the rhetoric, language, and contexts of English RAs. The field has now reached a point where its academic knowledge base regarding RAs is considerable, and a well-established pedagogy exists based on this knowledge. Future work in the field will be diverse, but the issue of making RA publication more democratic and less hegemonic will continue to occupy center stage for the foreseeable future.

Research Methods and Sociocultural Approaches in Second Language Acquisition

HOLBROOK MAHN AND SHANNON REIERSON

Since the publication of Frawley and Lantolf's 1985 study, there has been a significant increase in second language acquisition (SLA) research using sociocultural approaches that draw from Vygotsky's theoretical framework and methodological approach. Researchers interested in diverse facets of SLA both in and out of educational contexts have utilized sociocultural theory in a variety of ways. Some have focused more on the internal aspects of language, the mental processes involved in making and communicating meaning through language acquisition, while others have focused more on the social, cultural, physical, and historical contexts of second language learning and acquisition. While researchers have relied on different interpretations and aspects of sociocultural theory, they all strive to understand second language learning and acquisition considering the role of sociocultural *context* as a mediating force in language development and use. They also recognize the essential role of semiotic mediation—making meaning through signs—in the development of the mind.

Lantolf (2000, p. 18) draws on the memoir of one of Vygotsky's closest collaborators, Alexander Luria's *The Making of Mind: A Personal Account of Soviet Psychology*, to describe sociocultural approaches.

Because sociocultural research seeks to study mediated mind in the various sites where people engage in the normal activities affiliated with living, it undertakes to maintain the richness and complexity of "living reality" rather than distilling it "into its elementary components" for the purpose of constructing "abstract models that lose the properties of the phenomena themselves" . . . On this account, explanation of human activities is about observation, description, and interpretation guided by a theory that is careful not to compromise "the manifold richness of the subject." (Luria, 1979, pp. 174, 178)

Ever-developing systems of systems made manifold in complex, dialectical interconnections of mind and matter were the subject of Vygotsky's work. He advocated methods that were appropriate to the matter being studied—the unification of thinking and speaking processes—and not just methods borrowed from the natural sciences, which is what psychology had done in an effort to be recognized as an authentic field of science. He saw a dialectical relationship between theory and praxis in which testing theory in practice influenced the development of methodology.

The challenge faced by researchers developing sociocultural approaches to SLA research is similar to the one Vygotsky faced, since SLA research, in order to be accepted as a field, has also relied on methods developed by the natural sciences. In a special edition of the *Modern Language Journal*, Alan Firth and Johannes Wagner (2007) reflect back on their call ten years earlier for a reconceptualization of SLA, "for a theoretical, methodological, and epistemological broadening of SLA" to create "an SLA that was more interactionally sensitive, that also made room for an emic stance towards fundamental concepts, and that

took seriously the theoretical and methodological consequences of a social view of learning and language" (2007, p. 804). They called for developing a perspective that includes language users in their social, cultural, and historical contexts.

In this retrospective, Firth and Wagner also reiterate their position that sociocultural approaches should be included in SLA, but distance themselves from the use of the term *sociocultural* to describe their own work, as the "sociocultural approach has already established itself within SLA and is associated with the work of Lantolf and others" (Firth & Wagner, 2007, p. 814). They describe the theoretical foundation that Lantolf developed as he and "several collaborators . . . engaged in SLA theory-building in the Vygotskian tradition, producing what has become known as the sociocultural approach to SLA" (p. 805). The range of sociocultural SLA studies available today is a testament to James Lantolf's efforts in organizing and conducting research with students and colleagues and in developing collaborative efforts to disseminate, discuss, and analyze this important application of Vygotsky's work. These approaches seek to understand language acquisition in its manifold richness and draw on the experiences and introspections of second language learners, who learn language in very different contexts and situations of development.

The following overview does not attempt to give a comprehensive accounting of all of the work that has been done using Vygotsky's core concepts to investigate second language learning, teaching, and acquisition from a sociocultural perspective, but instead focuses on primary research that Lantolf and Beckett (2009) have highlighted and draws on the edited volumes of sociocultural research in SLA that Lantolf and his colleagues have compiled (Lantolf & Appel, 1994; Lantolf, 2000; Lantolf & Poehner, 2008), as well as books and articles that construct the theoretical framework that has guided sociocultural approaches to SLA (Lantolf & Thorne, 2006).

A challenge for sociocultural SLA research in constructing a methodological approach based on Vygotsky's theoretical framework is to recapture essential aspects of Vygotsky's overarching theory and methodological approach. A number of factors make this difficult, including: (a) Vygotsky's use of a dialectical approach based on the method of analysis developed by Marx and Engels; (b) the fact that his work was banned by the Soviet bureaucracy for twenty years, and that when it was "rehabilitated" interpretations of his work missed essential aspects; and (c) translation issues involving key concepts that are difficult to translate from Russian to English. Vygotsky examined the interconnectedness of all phenomena, "based on the concept that human activities take place in cultural contexts, are mediated by language and other symbol systems, and can be best understood when investigated in their historical development" (John-Steiner & Mahn, 1996, p. 191). The studies described below draw on these central concepts of Vygotsky's to guide research and to study second language learning through an examination of language use in different social and cultural contexts using a variety of quantitative and qualitative methods, including experimental, discourse analysis, self-report, text recall, case study, classroom based, longitudinal, historical/theoretical analysis, and others.

These methods reflect the wide array used in the broad range of studies investigating both L1 and L2 language acquisition. These methods are touched on in the descriptions of the sociocultural studies below. The focus, however, is on two aspects that make sociocultural approaches unique: first, the nature of the concepts being investigated, and second, the emphasis placed on the role of the context in which language learning is taking place. Lantolf (2000) has described how sociocultural approaches investigating SLA have focused on the main aspects/concepts of Vygotsky's work, including: mediation; inner speech, private speech, and internalization; the regulatory function of language; the zone of proximal development (ZPD) and scaffolding; testing, including dynamic assessment; and research methodology and theory. These concepts are used to organize an overview of sociocultural approaches to SLA research, starting with the concept of the ZPD.

Zone of Proximal Development

Vygotsky used this diagnostic principle to analyze the development of concept formation in children, often with an expert helping with the problem solving. He included peers as problem-solving collaborators in constructing meaning in the ZPD, but he did not investigate its relationship to adult learners. Vygotsky focused on analyzing the cultural development of children, looking particularly at the role that language played in the development of human consciousness. Therefore, his analysis did not go beyond the young adult. Sociocultural approaches to SLA research have expanded the application of this concept and shown its utility in analyzing the development of language learning and acquisition for adults.

For example, Aljaafreh and Lantolf (1994) conducted a longitudinal study with university students on feedback provided by an expert on learners' ZPDs and found that language development is a process that varies across learners, across proficiency levels, and across concepts or skills to be learned. Nassaji and Swain (2000) worked with two adults learning a second language and verified Aljaafreh and Lantolf's study, demonstrating that when L2 learners received relevant feedback within their ZPD, they were more likely to learn L2 article use. Also using the concept of ZPD to study adult L2 learning, Donato (Lantolf & Appel, 1994) examined peer dialogue and scaffolding within students' ZPDs as they collaborated to complete a difficult task. DiCamilla and Antón (1997) studied the role of repetition in collaborative writing sessions among adult L2 learners and found that repetition within their ZPDs helped scaffold the completion of their writing tasks. Using a microgenetic approach, de Guerrero and Villamil (2000) studied social interaction in peer revision during an L2 writing class with adults and found that the interaction helped to scaffold peer revision. "This study contributes to a greater understanding of the complex and intricate mechanisms that are at play during mediated interaction and highlights the behaviors that may facilitate or inhibit growth within the ZPD" (Lantolf & Beckett, 2009, p. 466). In three case studies of college-level L2 learners, Thorne (2003) documented the influence of the ZPD on students' Web-based dialogue and the use of different Web-based discussion formats that helped students succeed in communicating meaning for different purposes through different media.

Sociocultural researchers have also studied how an individual's self-reflection can create a ZPD for herself or himself. Verity (Lantolf, 2000) was able to use the concept of the ZPD to mediate the transition from being a successful teacher in the North American context to one in a Japanese context through writing in a diary. She described how conscious choices informed "her professional activity with the tenets of sociocultural theory, [and] awareness of the ZPD as a functional system motivated her to seek and create forms of self-mediation in a new and challenging environment" (p. 191). Kinginger (2002) conducted a historical review of the ZPD as it was interpreted in three different ways in its application to foreign language education in the United States. Kinginger's review was critical of some of the ways the ZPD had been appropriated into SLA research and in many ways reflected the critique of Dunn and Lantolf (1998) against those who wanted to equate the ZPD with Krashen's $i + 1$. As is reflected below, many sociocultural studies of SLA use the ZPD as they investigate other concepts of Vygotsky's.

Dynamic Assessment

An important consideration in using the concept of ZPD is the kind of assessment that can determine actual and potential levels of development. Lantolf (2008) describes how Luria developed psychological and educational measurements that avoided the pitfalls of

traditional approaches. "According to Luria, traditional assessments failed to differentiate between various groups of learners, offering only documentation of their poor performance. By co-constructing a ZPD with the learners, it was possible to uncover the source of their difficulties and to tailor an appropriate remediation program" (p. 16). A number of sociocultural researchers have applied dynamic assessment (DA) to SLA with a clear understanding of DA "as a development-oriented unification of assessment and teaching" (Lantolf, 2008, p. 17). A theoretical argument for the application of DA to SLA stresses that through such unification, educators are able to see that bringing a learner's "future into the picture requires mediation (i.e., instruction) that is sensitive to a learner's ZPD. Thus assessment without instruction overlooks the future, and instruction without assessment ignores the past, upon which the future is built" (Lantolf & Beckett, 2009, p. 470). Poehner (2008) gives an extensive overview of DA and reports on a number of studies, including, among others: (a) a longitudinal study using DA as a diagnostic tool to assess university L2 learners' abilities and achievements; (b) a study drawing on the work of Reuven Feuerstein, comparing DA to formative assessment, that concludes that formative assessment can be just as informative as summative assessment in determining learner development, if not more so; and (c) a study which looked at mediation and the ability to transfer what has been appropriated through mediation as two indicators of development and which found that DA was useful in assessing development in process.

Inner Speech

The concept of inner speech is an important component of Vygotsky's analysis of the unification of thinking and speaking processes resulting in verbal thinking. In differentiating his theory from the work of Piaget, who felt that egocentric speech in children disappeared, Vygotsky argued that instead of disappearing, egocentric speech is transformed into inner speech through internalization. Vygotsky studied inner speech in children as they developed their systems of meaning, but he did not study it in adults. Again, this is an area where sociocultural approaches to SLA research have taken a key concept and used it to understand second language learning and acquisition, especially with adult learners. Ushakova (Lantolf & Appel, 1994), using an "experimental-theoretical approach," examined the role of inner speech in SLA and concluded that because students relied only on L1 inner speech, L2 learners do not develop L2 inner speech. In spite of the controversial nature of this claim, Ushakova's study made a significant contribution to sociocultural approaches to L2 research with her assertion "that L2 learners rely on L1 meanings to organize the new language" (Lantolf & Thorne, 2006, p. 84.). Aneta Pavlenko's dissertation study looked at inner speech in immigrants and investigated its use in L2 acquisition by examining narrations by Russian and English L1 speakers about a three-minute film. She found that L2 learners used their new language to mediate their thinking. Pavlenko and Lantolf (Lantolf, 2000) later followed up on this study by conducting an analysis of documents in order to examine the experience of second language learners as they accommodated to the culture of the L2 and faced the loss of L1. In another dissertation study of second language learners, Holbrook Mahn (1997) used interviews, questionnaires, and written texts to examine students' attitudes toward the use of dialogue journals and the role of inner speech and verbal thinking as they made meaning through their writing. Antón and DiCamilla (1998) investigated the role of L1 in mediating thinking in L2 classrooms and the externalization of inner speech. A key function of inner speech is to help regulate thought and activity, a topic that is addressed after a description of another sort of regulatory speech: private speech.

Private Speech

This term applies to speech that is directed toward oneself but that, unlike inner speech, is articulated. While Vygotsky investigated egocentric speech, a type of private speech, most of the sociocultural studies on private speech have been conducted with adults. McCafferty (1994) examined self-regulatory private speech through a picture narration task and found that less proficient learners of L2 create more self-regulatory private speech than their more proficient peers. Swain, Lapkin, Knouzzi, Suzuki, and Brooks (2009), using quantitative and qualitative measurements, demonstrated through the use of pretests and posttests that private speech impacted the internalization and learning of concepts in L2. In a case study of private speech, Donato and McCormick (1994) demonstrated that language-learning strategies are learned as a result of socialization into a particular community of practice. Saville-Troike (1988) investigated ways in which children aged 3 to 8 years, who were native speakers of Chinese, Japanese, or Korean, used private speech to actively integrate their second language. She contrasted the use of the quantity and quality of the older children's use of private speech based on learning styles to that of younger children. Ohta (2001) conducted a case study of a university-level L2 classroom to describe how private speech supported the learning and internalization of the target language. She also described ways in which L2 learners were able to provide mediation within their peers' ZPDs. Centeno-Cortés and Jiménez-Jiménez (2004), in one of a small number of studies that have looked at the use of L2 to regulate thinking, gave complex cognitive tasks to participants in L2, showing that if students were able to use private speech in the L2, they were more successful on tasks than using L1 to complete the task. In a study of bilingual children, Smith (2007), through observations of interactive group activity and game playing, documented the private speech of ESL (English as a second language) children in bilingual contexts. The private speech produced by children was helpful in understanding what the children were learning and what their difficulties were.

The Regulatory Function of Speech

The way in which egocentric speech and inner speech are used to regulate thinking and activity was a central focus for Vygotsky, as it was for Frawley and Lantolf in their 1985 study—as noted above, generally considered to be the first application to SLA of a sociocultural approach based on the work of Vygotsky. Analyzing discourse generated by students providing oral narratives, Frawley and Lantolf showed how the linguistic features of oral narratives were demonstrative of the ability to regulate speech and thinking in L2 adults, as well as L1 children and adults, completing a difficult narrative task. A number of researchers following up on this study examined the language that was produced by L2 learners completing a task, both in the classroom and outside of it. Ahmed (Lantolf & Appel, 1994) used discourse analysis to examine cognitive regulation by focusing on tense marking in dialogue. Using two-way information gap tasks, Brooks and Donato (1994) analyzed the regulatory functions of speech between L1 and L2 speakers in collaborative tasks.

Gesture

Vygotsky maintained that an adult attributing communicative intent to an infant's grasping motion helped establish the social contact necessary for children to develop the pointing gesture as a symbol of their desires. The use of a symbol to communicate intention helped lay the foundation for the symbolic representation needed to communicate meaning through

language. Steve McCafferty (2002) was the first sociocultural researcher to look at the relationship between gesture and speech in L2 as well as at what gesture could reveal about internal speech and cognition. He examined the expression of motion events in L2 as a way to understand the relationship between speech and gesture, and focus on when expressions for motion vary from the L1 and L2. Jina Lee (2008) documented private speech and gesture in college-level ESL biology students and found that gestures accompanied by private speech helped students learn new scientific terms.

Social Situation of Development

As Firth and Wagner (2007) note, one of the major contributions that sociocultural approaches have brought to SLA research is the examination of the influence of context in studying SLA. Vygotsky insisted that all phenomena be understood as existing within social, cultural, natural, and historical contexts and developed the concept of *perezhivanie* (lived, emotional experience) to describe the relationship between an individual and the environment, broadly conceived to include social relationships. Key to his theory was the notion that the way in which individuals perceive, appropriate, understand, internalize, and emotionally respond to their experiences of interactions with their environment actually shapes the environment. Mahn and John-Steiner (2002) looked at the way that *perezhivanie* shaped L2 writers' ability to write in English.

Leo van Lier (2004), who has played a leading role in analyzing the centrality of context in language teaching, learning, and acquisition, has developed "an ecological perspective on language learning and teaching grounded in the principles of SCT and constructivist models of human activity . . . An ecological perspective compels us to reconceptualize learning as always and everywhere contextualized. Thus, not only do language and learning matter, but so do place, time, others, goals, and motives" (Lantolf, 2000, pp. 24–5). Negueruela's 2003 study marked the emergence of an orientation to SLA classroom-based research within a theory-as-educational-framework based on Vygotsky's conception of the dialectical unity between theory and praxis (reported in Lantolf & Beckett, 2009). Negueruela's research on his own L2 classroom utilized a sociocultural developmental model to support the learning, internalization, and subsequent communication of conceptual understanding as evidenced in three types of data: performance data, verbalization data, and data concerning explicit definitions of the linguistic features being analyzed. Negueruela found that meaning was more essential than linguistic factors.

Other sociocultural researchers have studied SLA in non-institutional educational settings. For example, Collignon (1994) studied Hmong individuals learning literacy through action research and described the need for a "culturally appropriate pedagogy" in which educators examine "the historical and social sources of learner's attitudes toward reading, writing, and thinking processes" (p. 331). She used a collaborative effort "with participants as informants rather than as subjects" and investigated literacy processes "in the fields, in homes and in classrooms where adults learn rather than in more traditional academic settings" (p. 331).

Historical/Theoretical

A key component of Vygotsky's approach to building a theory of psychological materialism was analyzing the prevailing theories about human consciousness for their strengths and shortcomings. The historical and theoretical work that has been central to sociocultural approaches to SLA research can contribute to this effort through a reconceptualization of Vygotsky's work. As noted throughout this entry, Lantolf's work has been instrumental

in establishing the theoretical framework for sociocultural approaches to SLA and for providing a historical perspective (Lantolf & Thorne, 2006). Other examples of historical/theoretical contributions include: Jane Zuengler and Elizabeth Miller on an overview of sociocultural and cognitivist approaches to SLA; Karen Johnson on sociocultural approaches to L2 teacher education; James Lantolf and Matthew Poehner on DA; Maria de Guerrero on a synthesis of research on the role of inner speech in second language learning and implications for teaching; Holbrook Mahn and Vera John-Steiner on Vygotsky's contribution to second language literacy acquisition, and Mahn on Vygotsky's system of meaning and L2 writers; the aforementioned work of Leo van Lier on an ecological perspective on L2 teaching; and William Dunn and James Lantolf on Krashen's $i + 1$ and Vygotsky's ZPD.

In summarizing their analysis of sociocultural approaches to SLA, Firth and Wagner conclude that

Much SLA research that has been produced over the last decade bears witness to a marked increase in the number of sociocultural and contextual-interactional themes and concepts impacting upon SLA's research agenda, revealing an apparent growing awareness of the need to take seriously the requirement for a more balanced approach to SLA research. (2007, p. 803)

The significant contributions of sociocultural approaches to SLA research and the way these approaches have helped expand what constitutes SLA research are evident even from the present brief overview. An important contribution to be made in the future will be to reconnect with the ambitious research agenda on which Vygotsky was working at the time of his death. Important in this reconnection will be a reconceptualization of Vygotsky's work which focuses on its essential aspects—*znachenie* (meaning) *slova* (word, that is, language) as a unit of verbal thinking and the system of meaning—analyzed in depth in Vygotsky's *Thinking and Speech* (1987). Such a reconceptualization would also open up avenues for using a sociocultural approach to investigate SLA throughout the different stages of child development, including that of children who are raised bilingually.

Research Methods and World Englishes

MARGIE BERNS

World Englishes (WE) is a multidisciplinary field, and as such involves a wide variety of research traditions. The approaches to inquiry adopted and the methodologies and techniques selected for gathering, analyzing, and interpreting data and information are as varied as the disciplines within which studies on the Englishes of the world are conducted. For example, social science-based investigations usually adopt qualitative and quantitative methodologies. More language-based projects may draw on descriptive and historical methods of information-gathering and analysis while literary studies may choose from dominant critical theoretical frameworks. Thus, an attempt at cataloging the research methods associated with World Englishes is not a straightforward task.

In the scientific community at large a distinction is often drawn between “basic (pure) research” and “applied (practical) research.” The former is generally associated with theoretical work that deals mainly with abstract constructs, while the latter is said to deal with concrete solutions to so-called “real world” problems. This characterization is, however, misleading because the boundaries between the two are not always clear, which militates against seeing the pair as an either/or proposition. A more accurate picture of the scope and nature of inquiry is rendered by regarding the two labels as opposite ends of a continuum (Perry, 2005). This view encompasses studies that are neither solely basic nor applied, but instead are more or less so and thus can be located at various points on the continuum between the two. This perspective also highlights the truth of the oft-cited maxim “there is nothing more practical than good theory,” as the fundamental work done in WE over the past 50 years aptly illustrates.

A prime example of basic research ongoing since the 1960s is that associated with the pioneering work of Braj Kachru (1965). Sometimes labeled the Kachruvian paradigm (Kandiah, 1996), this work resulted in the formulation of a theoretical framework that has come to serve as the foundation not only for applied studies in WE, but also as a further basic study tool. Key components of the framework are several constructs which have been reconsidered in the light of the changing nature of English-language learning and use around the world. Notions that have been revisited by Kachru and others (see, e.g., Kachru, 1992; Thumboo, 2001; Kachru, Kachru, & Nelson 2006) include the familiar triad of English as a foreign language, English as a second language, and English as an international language; the concepts of native speaker and non-native speaker; questions of linguistic model, language standard, and norm; and conceptualizations of a society’s norms of sociolinguistic appropriateness and a language user’s communicative competence.

Model building is another type of basic research represented in WE studies. The Concentric Circle Model of World Englishes (Kachru, 1985) was designed to capture the spread and development of the world’s Englishes from a geographical and historical perspective. It characterizes three main contexts of English learning and use, labels them as inner, outer, and expanding circles (nesting inside one another in this order), lists salient distinguishing features of each context, and identifies countries that share these features. With respect to its place on the basic-applied continuum, the circles model could be located closer to the middle point because it draws from and builds on the more abstract analysis of key concepts that preceded its design. Although the model is clearly practical for further

foundational and applied study, it represents an intermediate stage toward more concrete application in such fields as education, policy-making, or creative writing.

A quintessential application of basic research in language studies is to the everyday concerns of language teaching (in fact, at one time “applied linguistics” meant application of linguistic insights exclusively to teaching of languages). World Englishes research on pedagogical issues includes investigations of language-teaching methodologies, the appropriateness and effectiveness of methods designed for inner circle contexts when applied in expanding circle contexts; instructional models of communicative competence to serve as the foundation of communicative approaches to language teaching; or choice of English variety for the classroom model that learners are to aspire to, that is, an inner, outer, or expanding circle model of English.

Language policy is another area of applied research informed by what has been labeled “Kachruvian studies” (Bolton, 2005, 2006). Investigations have examined the social and cultural effects and implications of government sanctions against the use of new varieties of English, as with Singapore’s “good English” policy; the introduction of requirements for English instruction at the earliest stages of mandatory education, as carried out in China, Korea, and Taiwan, for example; or the linguistic and educational consequences of the No Child Left Behind Act on first-generation immigrant children in the USA.

The particular form that WE paradigm-based studies takes range from the exploratory to the empirical. Illustrations include empirical studies on the national uses of English; identification of main characteristics of English used for international communication at various linguistic levels; descriptions of registers in all types of media; development of extensive sociolinguistic profiles in various regions; comparison of contexts and methods of language teaching in diverse cultural and educational settings; study of local grammatical, linguistic, and literary traditions, and applications of the same to the analysis and description of World Englishes (Kachru, 1997).

In spite of the considerable influence of the Kachruvian paradigm and the extensive literature on multiple aspects of World Englishes done within its framework, it would be misleading to assume that everyone who engages in research on English bases their inquiries on its assumptions or shares its goals. English long has been explored, examined, and elaborated from a number of disciplinary orientations and with a variety of methodological strategies.

One means of understanding the complexity of the research territory WE covers and the array of perspectives on it is the classificatory scheme of approaches offered by Kingsley Bolton (2005, 2006). This classification systemizes disciplinary or subdisciplinary approaches taken by scholars and researchers, some of whom work within traditions from the late 19th century. It also includes the objectives and the exponents of each approach (see Table 1). As Table 1 shows, “Kachruvian studies” is but one of 11 extant areas in the field of language study that Bolton identifies as contributing to the expansion of knowledge about English and to the improvement of conditions related to its use and its learning.

The value of this scheme cannot be understated. It has significance for a general understanding of the research activities of those interested in the English language and also not only establishes World Englishes as a worldwide social, cultural, and linguistic phenomenon or as a paradigm associated with one school of thought, but also defines World Englishes as a broad field of inquiry that encompasses a range of traditions. Although Bolton sketches the objectives of inquiry within these traditions, his classification does not (nor was it meant to) describe how, for example, corpus linguists, lexicographers, or applied linguists interested in English in the global context go about gathering and analyzing information. In other words, what are their methods of inquiry? The following provides some examples.

The concern of English studies, as characterized by Bolton, is the specification of varieties of English from descriptive and historical perspectives. Concrete examples of how this is

Table 1 Approaches to World Englishes (from Bolton, 2005). Reproduced with permission of John Wiley and Sons

<i>Approach</i>	<i>Exponent(s)</i>	<i>Objective(s)</i>	<i>Timeline</i>
English studies	Quirk (1962, 1972, 1990), Burchfield (1985), Greenbaum (1985), Quirk & Widdowson (1985), McArthur (1992, 1998), Görlach (1995, 1998), Schneider (1997a, 1997b), and others.	To describe varieties of English from eclectic, descriptive, and historical perspectives. Situated against a tradition of English studies (Anglistik), dating from the late 19th century (e.g., the work of Otto Jespersen, Daniel Jones, and Henry Sweet).	1960s–present
English corpus linguistics	Greenbaum (1996), Nelson (1996), Meyer (2002), and others.	To provide accurate and detailed linguistic descriptions of World Englishes.	1990–present
Sociolinguistic approaches			
The sociology of language	Fishman (1972), Fishman, Cooper, & Conrad (1977), Fishman et al. (1996), and others.	To conduct research on English in relation to language maintenance or shift, ethnolinguistic identity, and so on.	1960s–present
A “features-based” approach	Trudgill & Hannah ([1982] 1994), Cheshire (1991), and others.	To describe varieties of English through dialectological and variationist methodologies. Situated against the long tradition of British and European dialectology.	1980s–present
Kachruvian studies	Kachru (1982, 1983, 1986a, etc.), Smith (1981, 1987), Lowenberg (1984), Gupta (1994), Pakir et al. (1994), Bautista (1997), Kirkpatrick (2002), Bolton (2003), Modiano (2003), and others.	To promote a pluricentric approach to World Englishes, highlighting both the “sociolinguistic realities” and “bilingual creativity” of Outer Circle (and Expanding Circle) societies.	1980s–present
Pidgin and creole studies	Reinecke (1937), Todd (1984), Mühlhäusler (1986), Romaine (1988), Holm (1988/1989), Sebba (1997), Mufwene (2001), and others.	To describe and analyze “mixed” languages and the dynamics of linguistic hybridization, beginning with the early work of Hugo Schuchardt (1842–1927).	1930s–present
Applied linguistics	Halliday, MacIntosh, & Stevens (1964), Stevens (1977, 1980), Brumfit (1982), Kachru (1982, 1986a, 1992a), and others.	To explore the implications of World Englishes for language learning and teaching.	1960s–present
Lexicography	Webster (1806, 1828) [USA], Yule & Burnell ([1886] 1969) [India], Butler (1981) [Australia], Orsman (1997) [New Zealand], Allsopp (1996) [Jamaica], and others.	To fulfill a range of objectives including the expression of a national linguistic identity (within the World Englishes context).	1980s–present
Popularizers	McCrum, Cran, & MacNeil (1986), Crystal (1995, 1997), and others.	To interest a mass reading public in issues related to World Englishes.	1980s–1990s
Critical linguistics	Phillipson (1992, 2000, 2003), Pennycook (1994, 1998), and others.	To express resistance to the linguistic imperialism and cultural hegemony of English. Derived from a Marxian political analysis or postcolonial theory.	1990s–present
Linguistic futurology	Graddol (1997) and others.	To predict future trends in the spread of English and English language teaching worldwide.	1997–present

done are the writing of grammars, comparing formal features of language varieties, recording the impact of contact between English and other languages, tracking linguistic changes over time, and investigating the notion of “good” and “bad” English. Although not included in Bolton’s framework, literary analysis of texts written in the world’s Englishes can be included under English studies. Analysis in contemporary studies may be guided by any one of a range of ideological perspectives, including the group of theories and perspectives that fall under postmodernism (Bertens, 2008), for example, postcolonial theory, critical theory, or feminist approaches. The methods of English corpus study research involve the collection of linguistic data, either written texts or transcriptions of recorded speech, and use of a variety of techniques, for example, computational, interactive, and manual, to code and analyze features. Lexicography, as the practice of dictionary making, involves compiling an inventory of words in a language and giving information on spelling, pronunciation, origins, definitions, history, and illustrations of use.

The sociology of language approach to WE employs case studies or questionnaire surveys, among other techniques common in the social sciences, as well as statistical analyses to research English in relation to such issues as the linguistic identity of social groups, social attitudes toward language, patterns and needs of national standard use, social varieties and levels of language, and the social basis of multilingualism. The features-based approach is another area of sociolinguistics that uses quantitative methods to find relationships. For example, using interviews, recordings, and observations, social class has been measured using any of a number (or combinations) of variables such as educational attainment, prestige, religion, gender, or power. Pidgin and creole studies may be theoretical or descriptive and use historical and sociolinguistic methods of analysis.

Bolton’s formulation of the objective of Kachruvian studies as the promotion of a pluricentric and socially realistic approach to WE rightly suggests that the methods of inquiry within this approach are diverse. Firmly grounded in linguistics in general, one method involves analysis of linguistic characteristics using linguistic models and terminology in a range of texts and media. Another method associated with this approach is drawing a sociolinguistic profile of English in a particular country or region to describe the functions, status, and users of the language as well as its historical and attitudinal context. Insights and inquiries into new English literatures also fall within the framework of Kachruvian studies. Examples are investigations of literature in English that has traditionally been excluded from the canon because it was written by an author outside the inner circle. These studies look at how these non-native speaker writers use local varieties of English to convey culturally specific meanings, the stylistic choices they make in their fiction, poetry, and drama. Also represented by a variety of methods is applied linguistics, which draws on both the hermeneutic and empirical paradigms. Interpretive studies include stylistic analysis and close readings of texts and documents. Quantitative studies may be experimental or non-experimental and qualitative inquiry may be represented by grounded theory, narrative, ethnography, phenomenology, or case study.

Critical linguistics adopts the hermeneutic paradigm and is represented by studies in linguistic imperialism, which focus on why and how a language becomes dominant, and in critical applied linguistics, which concerns the field of applied linguistics more generally. Central to this approach is taking a perspective that is always cognizant of the interrelated notions of power, inequity, and the connection between an individual’s identity and the capacity to make choices. Linguistic futurology uses sociolinguistic principles of the nature of language change and the techniques of scenario building commonly used by the military and by corporations to design plans for the future with respect to English. Popularizers use interviews, case studies, and other methods familiar to documentarians and journalists. Distinguishing this approach from the others is its use of language that is designed to be accessible to a non-specialist audience.

Given the number and variety of unanswered questions and unexamined issues that remain open with respect to English in the global context, there is plenty of room for all forms of research. As this overview of approaches taken to the study of World Englishes indicates, an array of viable paradigms, traditions, methods, and techniques are available in the quest to find answers and close gaps.

Research on Signed Language Interpreting

JEMINA NAPIER

As with interpreting research more generally, signed language interpreting (SLI) research is an emerging subdiscipline of translation studies. Earlier publications on SLI mirrored those on spoken language interpreting in being based on personal observations and experiential accounts. However, more recently we have witnessed a “mini-explosion” of SLI research that is both quantitative and qualitative in nature, and across various domains of interpreting. The research is predominantly conducted in the USA, UK, and Australia, although examples can also be found from Canada, Italy, France, Austria, Ireland, Brazil, Sweden, and more recently China. There is also more evidence of international collaboration among signed and spoken language interpreter researchers.

SLI research is now widely accepted as informing our understanding of interpreter-mediated communication in all languages, not just those using a signed language. It should be noted, however, that the majority of SLI research reflects the settings in which SLI mostly occurs – in the community. Very little research has been conducted on signed language conference interpreting, as this domain forms a very small proportion of the work of signed language interpreters. This situation is changing as more deaf people obtain university qualifications and employment in professional roles that necessitate their attendance at conferences. With the growth of conference SLI provision, we may see more interest in conference SLI research.

Grbic’s (2007) bibliometric analysis of SLI research provides an interesting picture of the research that has been conducted over the years. In developing a database of SLI literature, Grbic analyzed 908 research texts produced from 1970 to 2005. She found that there has been a significant increase in production over that time, with an acceleration in the mid- to late 1990s. The majority of texts were published as journal articles or collective volumes, and were distributed over various key themes. The themes include discussions of settings and modes, professional issues, quality issues, ethics, role and sociocultural issues, linguistic issues, cognitive issues, and research issues. In her conclusion Grbic states that “The data revealed that research into SL interpreting can contribute to the enhancement of knowledge, and to the general understanding of interpreting as a topic of scientific research” (p. 45).

Metzger (2006) and Napier (2011) have both presented overviews of SLI research publications and theses in their general discussions of SLI. Gallaudet University Press has introduced a *Studies in Interpretation Series* with volumes featuring quantitative and qualitative SLI research and several other volumes have been published which collate discussions of SLI research (see Suggested Readings). Furthermore, the *Sign Language Translator and Interpreter*—a research-focused journal published by St. Jerome—has now been converted into a book series.

SLI research has adopted four main approaches to the majority of research studies: (a) a discourse analytic approach (transcriptions of naturally occurring data); (b) an ethnographic approach (focus groups, interviews, field observations); (c) survey research (questionnaires); and (d) an experimental approach. More SLI practitioners are becoming involved in conducting action research engaging in reflective practice, which has been

referred to as “interpreter fieldwork research” (Napier, 2011). Due to the relationship between interpreters and the deaf community and to language–culture dynamics between a majority language and a minority culture, a lot of emphasis is placed on ensuring that deaf consumers are satisfied with SLI provision. This has influenced a stream of SLI research that explores deaf consumer perceptions of SLI. Although SLI research covers a range of domains, it is not possible within the scope of this entry to cover them all. So here a snapshot will be presented of the key areas of the most prolific research domains. Readers can access more detail on the range of research by consulting the suggested readings.

Research Domains

Role and Ethics

Some SLI research concerns discussions of the role of the interpreter and ethical decision making. The work of Melanie Metzger (1999) has been particularly groundbreaking in analyzing the role of the signed language interpreter, and also of community interpreters more generally. She conducted a sociolinguistic analysis of two American Sign Language (ASL) interpreter-mediated interactions and “deconstructed the myth” that interpreters retain a neutral stance. Other authors have questioned the nature of codes of ethics, and the application of codes to professional practice and the impact on perceptions of the role of the interpreter. For example, in a survey of British Sign Language (BSL) interpreters, Tate and Turner (1997) presented a series of ethical dilemmas and analyzed interpreter responses to those dilemmas. They found the (then) British SLI code of ethics seemed to disable interpreters by encouraging them to respond in certain ways, when in fact they knew an alternative approach would be more effective even if it seemed to contravene the code. As a consequence, they suggested that the code should be revised to reflect current demands placed on interpreters. A more recent research-based approach to ethical and professional decision making in SLI has been put forward by Dean and Pollard (2001), who propose a *demand-control schema* (DC-S) to examine the complex occupation of SLI. Demand-control theory is a job-analysis method useful in studies of occupational stress and reduction of stress-related illness, injury, and burnout. Dean and Pollard have adapted the theory to apply to SLI, and describe sources of demand in the interpreting profession, including paralinguistic, environmental, interpersonal, and intrapersonal demands. They suggest that interpreters can use *decision latitude* and implement various controls to deal with the demands placed upon them. Dean and Pollard have carried out various pieces of research with interpreter educators and consumers to inform the development of the DC-S and establish how it can be applied in SLI education.

Profile

A range of demographic surveys have been conducted in order to develop a profile of the SLI profession worldwide. One of the first surveys was administered in the USA (Cokely, 1981) and presented a picture of signed language interpreters as typically females who work part time. This finding has been confirmed time and again in various other surveys in Canada, the UK, Australia, and Austria, to name but a few. A more recent survey in China has shown that SLI is still very much an emerging profession.

Interpreting Process and Product

Various research studies have been conducted that focus on the SLI process, and typically draw on psycholinguistic or sociolinguistic frameworks. For example, early psycholinguistic research looked at working memory in ASL interpreters (Isham & Lane, 1993), but this

has never been explored further. Dennis Cokely (1992) presented a sociolinguistic model for SLI based on his research of interpreters' time lag. Cynthia Roy (1989) broke new ground with her sociolinguistic analysis of SLI as a discourse process, and her work has led the way for other research on interpreter-mediated interaction. In the last decade or so sociolinguistic analyses have become more popular. There is therefore a great need for more psycholinguistic research to enhance our understanding of the SLI process on both a cognitive and a communicative level.

The interpreting process has also been innovatively explored in relation to the process of cooperation that occurs between two interpreters working together, or the cooperation and co-construction of meaning between interpreters, deaf and hearing interlocutors in monologic and dialogic settings (e.g., Cokely & Hawkins, 2003).

Alternatively, in evaluating the SLI product, comparative text analyses have been carried out on monologic interpretations into a signed language from a spoken language (e.g., Winston & Monikowski, 2003). These studies typically focus on accuracy, omissions, additions, or use of discourse markers, and several have discussed evidence of language contact between spoken and signed languages in interpretation.

Educational Interpreting

By far the largest domain of SLI research is on educational interpreting. Several survey-based research studies have shown that a large proportion of SLI work is in education, and discuss perceptions of role conflict for educational interpreters, rather than the analysis of accuracy or effectiveness of educational interpreting (e.g., Fleetwood, 2000).

More recently, SLI scholars have begun to question the effectiveness of interpreting for children's education, demanding more research and discussion. Aside from the development of, and research into the outcomes of, an educational interpreter performance assessment in the USA (Schick & Williams, 2004), there is very little empirical evidence regarding how well deaf students actually understand interpreters or experience their education through interpreter mediation.

One of the very few authentic qualitative classroom-based case studies of educational interpreting was conducted by La Bue (1998), who analyzed and compared teachers' and interpreters' utterances in a ninth-grade English class, and analyzed discourse markers, their functions, and the way they were interpreted, as well as equivalence of vocabulary and meaning. The interpreters in the study did not convey the footing shifts of the teacher, and therefore the deaf child did not receive the "invitation" to participate in discussion.

Aside from the issues in working with children in educational settings, signed language interpreters also now face the challenge of mediating tertiary education for deaf adults at all levels. Several ethnographic, linguistic, and experimental studies have investigated elements of university SLI, including strategies used by lecturers, deaf students, hearing students, and interpreters to fulfill their roles in the learning process (Harrington, 2005), and comprehension of interpreted lectures (Marschark, Sapere, Convertino, Seewagen, & Maltzen, 2004).

Legal Interpreting

Another central research domain sees a plethora of papers on legal SLI, with analyses of the interpreter role or SLI-mediated discourse in the courtroom, discussions of potential linguistic barriers that deaf people face in the legal system, and exploration of whether deaf people can serve as jurors. Here an overview is given of two major studies to date on SLI in court.

Brennan and Brown (1997) conducted a multimethod study of deaf people's access to justice in the UK through the observation of BSL interpreters working in court, a survey

of legal interpreters, and interviews with deaf people and interpreters about their legal interpreting experiences in police, court, and other legal settings. They highlight the fact that signed language interpreters experience conflict in terms of perceptions of their role; but the most interesting aspect of their study is their discussion of linguistic issues. In addition to the linguistic and discourse challenges faced by interpreters of all languages, SLI occurs bimodally, that is, between two languages that are expressed in different modalities. They found that the level of visual encoding required in BSL provided a challenge for BSL interpreters in relation to the use of superordinate terms which often come up in court, such as “murder,” which do not have one established sign in BSL.

In her study of ASL interpreters in Canada, Russell (2002) conducted four mock trials with real judges and lawyers, some with experience of working with spoken and signed language interpreters, and interpreters worked in either the consecutive or the simultaneous mode. Three different discourse events were analyzed: (a) entering of direct evidence, (b) cross-examination, and (c) expert witness testimony. Russell found a statistically significant difference in terms of accuracy, with simultaneous interpretations 87% accurate, as compared with consecutive interpretations, which were 95% accurate.

Posttrial interviews with participants revealed that the lawyers and judges seemed to prefer experiencing interpretation in the simultaneous mode, especially during the cross-examination (for the lawyers). They stressed the importance of preparation with interpreters, and that interpreters should request permission from the judge to clarify information, or consult with one another. Deaf witnesses said that interpreters should be confident and well prepared, whereas the expert witness felt that it was important to prepare with interpreters, and commented that they did not seem comfortable using the consecutive approach or note taking. The interpreters also stressed the importance of preparation, and recognized that the quality of their interpreting was better when they used the consecutive mode.

Medical and Mental Health Interpreting

An emerging body of work in SLI research concentrates on the medical and mental health domains, although it is still relatively small. The findings overlap heavily with results from spoken language research on interpreter-mediated communication in medical or mental health contexts, in terms of the interpreter not being “invisible.” Primarily, discussion has been based on personal reflections of practitioners, and to date Metzger’s study is the only published discourse analytic case study of medical SLI based on authentic data. Several papers have documented health-care professionals’ or interpreters’ views on interpreting in health care, with data primarily gathered through surveys, interviews, focus groups, or desk research of databases (e.g., Smeijers & Pfau, 2009). Discussions of mental health SLI are also dominated by personal observations of interpreters and therapists, as opposed to research; however, some interesting research projects have emerged that document the process of, and issues in relation to, translation of psychological or psychiatric standardized assessment instruments into signed languages (Montoya et al., 2004). As detailed in the following section, signed language translation (SLT) is an emerging complementary area of research in the SLI field.

Signed Language Translation (SLT)

Until very recently, no one had given consideration to the fact that, although signed languages do not have a written form, it is possible to translate between a written language and a signed language. Since that time, several papers have been published concerning discussions of SLT of a range of texts from a written language into a signed language; for example, psychological test instruments (as mentioned above), educational assessment tools, children’s books, or academic texts. Others have discussed the translation of signed

texts into written documents, such as the dictation of letters, narratives, or community information.

Although more research is needed, Leneham (2007) has argued for a different approach to the typological descriptions of translation and interpreting, and that we should move away from the focus on the language mode (i.e., written, spoken, signed) and focus instead on the process. Leneham argues that the key is in the preparability and potential for correction, and whether the target text is captured for posterity, and documents six SLT processes that can be considered as separate from SLI. This area of research is breaking new ground in the SLI field.

This entry has provided an overview of some of the key research domains in SLI research. Readers will notice that many of the references date from 1990 or later. This is a telling aspect of SLI research in that, although publications discussing SLI commenced much earlier than the 1990s, very little data-driven research was available until much more recently. Much more research is needed to understand the processes and products of SLI in more detail, and the similarities and differences between spoken language and signed language community interpreting, conference interpreting, and translation.

Research Techniques and the Bilingual Brain

BARBARA T. CONBOY

Introduction

Bilingualism—broadly defined as the regular use of two or more spoken or signed languages in a person's daily life—is frequent throughout the world, yet many models of how language is acquired and processed by the brain have been based on studies of monolingual children and adults. Practical need for normative data, and theoretical interest in the uniqueness of bilingual language processing, have increased the demand for research on the bilingual brain. At the same time, techniques for investigating the neural bases of language across age groups continue to develop, making the neural basis of bilingualism a promising area for future research.

Traditionally, basic research on the bilingual brain has addressed three main themes: (a) the functional organization of the neural systems involved in perceiving, storing in memory, comprehending, and producing each language of bilinguals; (b) structural or functional differences, or both, between monolingual and bilingual brains; and (c) the relative roles of maturational constraints on language acquisition (i.e., “critical periods”) and proficiency levels in differences in brain organization within or across individuals. Recent advances in methodology have allowed researchers to address these issues in new ways—for example, studying the spatiotemporal dynamics of processing each language—and to extend their studies to very young children and infants.

This entry provides an overview of research techniques used to study how two languages are acquired and processed by individuals who learn a second language (L2) early in childhood, at roughly the same time as their first language (L1) (“simultaneous” or “early” bilinguals) and those who learn the L2 after the L1 has been mostly acquired (“sequential” or “late” bilinguals). These include clinical studies of individuals with brain pathologies, behavioral methods used to study the cerebral lateralization and organization of language functions, and current brain imaging techniques developed within the growing field of cognitive neuroscience. Key findings from studies of bilingual adults and children, and infants raised with dual language exposure, are provided. For a deeper understanding of each technique and specific examples of the research findings each has yielded, the reader is referred to available review papers and books on these topics.

Studies of Clinical Populations

The question of whether two languages are represented, processed, or both in distinct neuroanatomical systems was initially addressed through case studies of bilingual adults with neuropathology. Although findings from clinical populations cannot be generalized to normally functioning populations, they have provided information about the areas of the brain essential for language functioning, and have helped develop hypotheses subsequently tested using experimental methods with healthy individuals.

Bilingual Aphasia

The term “aphasia” is used to describe any disorder that primarily affects specific language functions and is acquired through some form of brain injury, usually a focal brain injury. Prior to the availability of neural imaging techniques, aphasiology research relied on the correspondence between patients’ behaviors and post-mortem analyses of brain anatomy in order to infer functional specializations for language. Such initial studies indicated that left perisylvian areas of the cerebral cortex (the inferior frontal and posterior temporal lobes) are essential for normal language functioning in all but a small percentage of individuals who have right hemisphere dominance for language. These findings have been replicated using modern imaging methods, though subcortical and right hemisphere areas are now acknowledged to also play important roles in normal language processing (see Fabbro, 2001; Paradis, 2004; Hull & Vaid, 2006).

Reports of bilingual and polyglot patients who showed differential impairment and recovery in each of their languages after brain injury began to appear in the scientific literature as early as the late 19th century. These observations led to the following major proposals regarding the functional organization of the bilingual brain: greater right-hemisphere involvement for both languages than in monolinguals; greater right-hemisphere involvement for L2 than for L1 processing; and involvement of separate as well as overlapping areas of the left hemisphere for both the L1 and L2. Subsequent research on aphasic patients and normally functioning bilinguals has indicated that the age of L2 acquisition, relative proficiency of the L1 and L2 (or the dominant and nondominant languages), and the frequency of use of each language affect cerebral specialization for language functions (e.g., Hull & Vaid, 2006). One current explanation for different patterns of impairment/recovery across languages is that L2 grammatical knowledge is often acquired through formal instruction rather than through the naturalistic, informal learning typical of L1 acquisition, is not incorporated into an individual’s implicit linguistic competence, and does not become available for automatic use. Thus, depending on the site of a patient’s lesion, and the extent to which L2 functions have become automatic through frequent use, functioning may be more severely affected in the L1 than in the L2, or vice versa. Cases of paradoxical recovery, in which a less dominant L2 is relatively spared after injury, may be explained by greater reliance of the L2 on explicit (declarative) memory processes, and lesser reliance on areas involving implicit (procedural) learning and automaticity (see Fabbro, 2001; Paradis, 2004).

Studies of aphasia have also led to proposals regarding control over the use of two languages in bilinguals. It has been proposed that disruption to an executive control mechanism located in frontal and prefrontal areas can lead to imbalances in the amounts of inhibition and activation of each language, leading to fluctuating performance across languages. Much recent work on the neural bases of normal as well as disordered language in bilingual individuals has focused on control over language switching and translation, or on levels of activation of each language (see Fabbro, 2001; Rodríguez-Fornells, Balaguer, & Münte, 2006; Abutalebi & Green, 2008).

Clinical Intra-Operative Studies

Case studies of patients undergoing brain surgery to remove tumors or areas affected by seizures have also provided insights into the organization of the bilingual brain. A pre-surgical clinical tool known as the “Wada test,” in which a barbiturate (sodium amobarbital) is injected into the right or left carotid artery to temporarily disrupt function in the ipsilateral cerebral hemisphere, has been used to determine patients’ cerebral dominance for cognitive functions. This test, and several other techniques (described below), are forms of a “virtual lesion” approach in which the effects of a lesion are simulated so that areas

essential for cognitive functions may be identified. In one early study, Rapport, Tan, and Whitaker (1983) reported on four polyglot patients for whom naming in both languages was significantly disrupted during temporary inhibition of the left hemisphere, but remained highly accurate during inhibition of the right hemisphere.

By the latter half of the 20th century, improvements in surgical procedures made it possible to perform a more precise “virtual lesion” test than the Wada test via direct electrical stimulation of discrete areas of the cortical surface or subcortical areas while an awake patient was engaged in a task. Direct electrical stimulation of neural tissue temporarily disrupts that area’s function, simulating the effect of a focal lesion and allowing a high-resolution localization of the areas essential to that function. Intra-operative studies using direct stimulation have shown that bilingual individuals’ two languages are represented in overlapping areas within the general language regions, and that the organization of two different languages within the brain may be affected by relative proficiency and use of each language, above and beyond the age of L2 acquisition. For example, stimulation of many regions in left frontal and temporal areas disrupts object naming in both languages of patients; however, there are also regions where stimulation affects only one language (for review, see Rodríguez-Fornells et al., 2006). Disruptions of language behaviors over less diffuse areas of cortex for the stronger than for the weaker language, regardless of age of L2 acquisition or whether the stronger language was the L1 or L2, led to the proposal that as an individual develops competence in a language, smaller cortical areas are needed for processing that language. Both the Wada test and cortical stimulation of left hemisphere areas have also been shown to induce disruptions in language control, in the form of involuntary switching from one language to the other (Kho et al., 2007).

Studies of Normally Functioning Populations: Behavioral Methods

Given the invasiveness of methods used intra-operatively, and problems with generalizing findings from clinical populations to normal populations, non-invasive methods have been devised for studying the organization of the brain for language processing in individuals with intact brain function. These methods can be broadly divided into behavioral and neural imaging techniques. In the following sections, several widely used behavioral techniques are briefly described.

Behavioral Techniques That Measure the Lateralization of Language Functions

Visual half-field, dichotic listening, and manual interference paradigms have been used to determine whether bilingual individuals show the same amounts of left-hemisphere dominance for L1 processing as monolingual individuals, and whether laterality patterns are similar for the L1 and L2 within individuals. Prior to the availability of modern functional neural imaging techniques, researchers devised experiments to determine laterality patterns by capitalizing on the nature of ipsi- and contra-lateral connections between higher-level processing mechanisms in cortical areas and peripheral sensory and motor mechanisms. For example, information presented to either visual field or ear is processed in the contra-lateral cerebral hemisphere before it is transferred to the ipsi-lateral hemisphere. In visual half-field experiments, an instrument called the “tachistoscope” limits the viewing of printed language or other visual stimuli to the left or right visual field, to isolate whether linguistic information is processed first in the right or left hemisphere. Similarly, in dichotic listening tasks, stimuli are presented concurrently to the left or right ear, and subjects repeat or write what they remember. In individuals with left-hemisphere dominance for

language, faster or more accurate processing occurs when language stimuli are presented to the right versus the left visual field or ear. In manual interference paradigms, a subject taps with the right or left hand while performing a verbal task, and the tapping rates for each hand are compared to baseline rates (tapping without doing a verbal task) for the same hand. Interference, in the form of a slowing of tapping rate, occurs for the hand contra-lateral to the language-dominant hemisphere.

Several studies using these paradigms have shown differences in bilingual and monolingual individuals and between languages within bilingual individuals. However, a meta-analysis showed that the results across studies support similar left-hemisphere dominance for language in late bilinguals as in monolinguals, except when L2 proficiency is low, and greater bilateral involvement for both languages in early bilinguals (Hull & Vaid, 2006).

Behavioral Techniques That Measure the Speed and Accuracy of Processing

Reaction time and eye-tracking procedures have been used to study whether the speed and accuracy of processing language stimuli differs for bilingual and monolingual individuals, for each language within bilingual individuals, and when phonological or semantic primes are available within and across languages. Such methods have been used to test models of the functional organization of language and the role of cognitive control processes in bilingual processing (for reviews, see Marian, Spivey, & Hirsch, 2003; French & Jacquet, 2004).

Reaction times, measured using button presses or eye movements, can be used to determine how quickly subjects access various types of linguistic information, such as verifying whether or not a word and picture presented simultaneously match, choosing which of two pictures matches a spoken or written word, deciding whether a string of spoken speech sounds or written letters is a word, and detecting semantic or syntactic violations in sentences. Voice activation can be used to measure the speed with which subjects name pictures depicting objects or actions, switch between languages, or translate words from one language to another. Priming experiments, in which the speed of producing or recognizing a word preceded by a related word (prime) in the same or other language is studied, and translation paradigms, in which speeds of translation from the L1 to the L2 and vice versa are compared, have shed light on the organization of the bilingual lexicon. Speeds of L1 and L2 processing, in mixed and single language conditions, have also been used to study language organization and control mechanisms. Eye-tracking paradigms have recently begun to be used with young bilingual children (Marchman, Fernald, & Hurtado, 2010).

Studies of Normally Functioning Populations: Neural Imaging Methods

Recent advances in cognitive neuroscience have allowed researchers to non-invasively study the spatiotemporal dynamics of language in groups of healthy individuals as well as those with neural pathologies using measures of ongoing brain activity and brain structure. Neural imaging techniques go beyond behavioral methods for studying the functional organization of the bilingual brain as well as differences in function and structure between bilingual and monolingual brains. Electrophysiological methods allow more precise recordings of the temporal aspects of real-time language processing than do behavioral techniques. Methods that involve imaging metabolic changes in brain tissue active during language tasks allow for a precise localization of language functions not possible with behavioral methods. Neural imaging can also complement behavioral methods for studying the mechanisms underlying bilingual individuals' control over their two languages.

While the neural imaging literature has grown tremendously over the past two decades, developmental neural imaging studies remain comparatively sparse due to limitations in the methodologies that can be used with infants and young children. For young children, electrophysiological studies remain the most popular method for studying language processing, although such studies also present methodological challenges and are relatively rare. Other promising techniques currently being applied to infants and young children are various forms of optical imaging. Neural imaging studies with infants and children being raised with two languages are extremely rare. In the following sections, several current functional neural imaging research techniques are reviewed, and examples of results are summarized. Excellent recent reviews of studies conducted with adults are available elsewhere (e.g., Paradis, 2004; Indefrey, 2006; Chee, 2009; see also Suggested Readings).

Transcranial Magnetic Stimulation (TMS)

TMS is a “virtual lesion” approach that is less invasive than direct cortical stimulation, and thus has allowed researchers to determine the areas essential for language functioning in groups of healthy individuals. In TMS, rapid changes in a magnetic field (pulses) next to the scalp induce a weak electrical current that activates neurons on the surface of the cortex just under the skull at the site of stimulation and can temporarily interrupt normal brain activity in that region. Although this stimulation is not spatially precise, the induced currents can be related to sites of activation within a few millimeters. When a TMS pulse is applied to an area while a subject performs a task, and performance on the task is momentarily disrupted, this is evidence that the area is essential for performing the task. TMS can also induce particular behaviors. For example, application of TMS to the dorsolateral prefrontal cortex in bilingual individuals undergoing treatment for depression unexpectedly induced an involuntary switch to the other language (Holtzheimer, Fawaz, Wilson, & Avery, 2005).

Positron Emission Tomography (PET)

PET was one of the first functional neural imaging techniques applied to the study of language and bilingualism. In PET, a radioactive substance injected into the bloodstream moments before a subject completes a task is imaged in the areas of the brain that are most active during the task, because of regional cerebral blood flow (rCBF) to those areas. For example, in one of the earliest functional neural imaging studies of bilingual adults, Klein and colleagues reported that PET showed the same activation in left inferior frontal areas for the L2 as for the L1 across several production tasks (Klein, Milner, Zatorre, Meyer, & Evans, 1995). However, greater activation (rCBF) was seen for the L2 in the left putamen, a subcortical structure involved in the phonological and articulatory aspects of speech, even though subjects were highly proficient in the L2.

Functional Magnetic Resonance Imaging (fMRI)

Because of its less invasive nature, fMRI is now more commonly used than PET for language studies of healthy individuals. In fMRI, hemodynamic (blood flow) responses in brain regions that occur several seconds after the firing of neurons indirectly measure brain activity. Because of this lapse, fMRI (like PET) does not measure brain activity with precise temporal accuracy, but is remarkably good at localizing primary regions of activation. Over the past two decades, numerous studies of bilingual adults and L2 learners have been conducted using fMRI, and these have indicated functional separation as well as overlap between languages, depending on the task and language histories of participants.

The fMRI technique has also been used to study the locus of control over language switching and translation in bilingual adults, and functional differences between bilinguals and monolinguals on nonlinguistic tasks. Given that fMRI requires subjects to remain nearly motionless, it is difficult to conduct such studies with young children. To date, there are no published fMRI studies of bilingual infants or very young children as they process language, and only a few studies with older bilingual children (e.g., Mondt et al., 2009).

Event-Related Potentials (ERPs)

ERPs are averaged epochs of brain electrical activity that are time-locked to the onset of a stimulus and thus ideally suited for studying the time course of the neural activity linked to language processing on a millisecond-by-millisecond basis. Due to the spreading of electrical potentials through the skull before they are recorded at the scalp, ERPs do not offer the precise information about where processing occurs that is possible with fMRI or PET, but they offer better temporal resolution and are more direct measures of brain activity. ERPs to language stimuli are typically characterized by a series of positive and negative waveforms peaking within the first few hundred milliseconds after stimulus onset, each of which reflects different sensory, perceptual, and cognitive processes during various stages of processing. The distribution of these components across the scalp, and the synchronization of particular frequency ranges of brain activity across different areas, may also be used to study functional specializations for aspects of processing. ERPs have been used to address questions about the relative speed of processing of each language, the functional specializations for different language processes (phonology, semantics, syntax, etc.) that vary with age of L2 acquisition and proficiency, and the cognitive-linguistic processes involved in translation and language switching (for reviews, see Moreno, Rodríguez-Fornells, & Laine, 2008; Kotz, 2009).

In addition to their temporal sensitivity, a strength of ERPs is that well-established components indexing language processing can be studied across different ages, including very young infants. For example, speech discrimination studies of children using variations on the same basic ERP paradigm that has been used with adults have revealed how age and experience with language affects the development of a mismatch response to phonemic contrasts in infants acquiring two languages simultaneously (García-Sierra et al., *in press*), infants with short-term L2 exposure (Conboy & Kuhl, 2010), and children in L2 educational settings (e.g., Rinker, Alku, Brosch, & Kiefer, 2010). ERPs have also revealed differences between bilingual and monolingual word processing in infants and children, and shown how word processing varies across and within children as a function of language experience, the phonological characteristics of each language, and the cognitive demands of processing language switches (Conboy & Mills, 2006; Vihman, Thierry, Lum, Keren-Portnoy, & Martin, 2007; Kuipers & Thierry, 2011).

Magnetoencephalography (MEG)

MEG, in which magnetic fields created by neural activity are measured at the scalp, is ideally suited for studying the neural bases of language processing because it has the same high temporal sensitivity as ERP but better spatial sensitivity given that magnetic fields are not distorted before they reach the scalp. Due to high operating costs, MEG is not as widely used in language research as ERP. One recent study of bilingual adults used a combined MEG and structural imaging approach to localize stages of written word processing in each language (Leonard et al., 2010). In other research, MEG used with adults during a nonverbal conflict task revealed different loci of control in bilinguals and monolinguals (Bialystok et al., 2005). To date, no MEG studies of bilingual infants or children have been published.

Near Infrared Spectroscopy (NIRS)

NIRS is a non-invasive optical imaging technique that indirectly measures neural activity by detecting changes in deoxygenated and oxygenated hemoglobin concentrations in the blood flow to activated areas from the absorption of infrared light measured at different wavelengths. Although NIRS is not as widely used as fMRI, it holds more promise for use with infants and young children because it is less sensitive to movement artifact. Research using NIRS has yielded both similarities and differences in the regions involved in language processing in bilingual adults, and work is currently being done with infants exposed to two languages (see Petitto, 2009).

Structural Imaging Techniques

The use of structural magnetic resonance imaging has allowed researchers to examine the long-term impact of speaking two languages on brain structure. Although a few structural imaging studies of bilingual children with neural pathologies are available (e.g., Mariën, Abutalebi, Engelborghs, & De Deyn, 2005), published structural studies of neurologically normal bilingual individuals are currently limited to adults.

A technique known as “voxel-based morphometry” (VBM) assesses differences in the composition of brain tissue after eliminating macroscopic differences in the shape of the brain, and can distinguish between gray matter (nerve cell bodies and unmyelinated axons and dendrites) and white matter (myelinated axons that connect neurons) (Green, Crinion, & Price, 2007). Studies using VBM have suggested that changes in the density of gray matter are linked to proficiency in an L2 and the age at which the L2 was acquired (e.g., Mechelli et al., 2004; Green et al., 2007). Experience-dependent changes in the structure of the corpus callosum in bilingual adults have also been reported (Coggins, Kennedy, & Armstrong, 2004).

Summary

A main finding of many of the studies reviewed above is that both the age of acquisition of a language and experience with that language affect the functional organization of the brain for language processing, and can also affect brain structure. A limited number of studies with infants and children being raised bilingually have also shown that, even when two languages are acquired early, the brain systems involved in processing each language vary according to relative language proficiency. Structural and functional differences between bilingual and monolingual individuals are strong evidence of the experience-dependent nature of brain development in humans, and suggest that readers must exercise caution when interpreting data from functional neural imaging studies in which predetermined regions of interest are compared across individuals. Moreover, information about the areas essential for normal functioning in all of an individual’s languages is crucial for clinical decision making.

Prospective studies of the development of brain structure and function in children as they acquire two languages are needed. The study of bilingual children can inform how experiential factors influence the organization of two different languages within the same brains over time. Neural imaging methods also facilitate study of the cognitive mechanisms employed for those aspects of language processing that are unique to bilingualism or multilingualism (language control, switching, and translation). Another promising approach is to investigate how the amounts, timing, or locus of brain activity change over time by using similar paradigms in cross-sectional studies (across various ages), and in longitudinal studies (at various stages of L2 acquisition). Such research is expected to increase in the coming years, and will add to the growing literature on the bilingual brain.

Researcher Reflexivity

SUE STARFIELD

At a recent conference on discourse, one of the keynote speakers remarked during her presentation that the reviewer of a paper she had submitted for publication in an academic journal had asked for “more reflexivity.” What could this throwaway comment have meant? This entry aims to help readers think about what researcher reflexivity might mean and what the reviewer might have had in mind.

Until fairly recently, social science research was characterized by its objectivity, particularly the objectivity of the researcher him-/herself. With the decline of positivism, and the rise of qualitative research methodologies, the researcher is no longer seen as a source of bias or error whose presence may interfere with the presentation of an objective social reality.

Well-known sociolinguist, William Labov, coined the phrase the “observer’s paradox” as he tried to reduce what he perceived to be the interference caused by the presence of the researcher in the collection of speech data. The paradox lay in his trying to find out how people spoke when not being systematically observed; however, the only way to study this was to observe them (Labov, 1972, p. 209). While Labov devised various methods to reduce the perceived influence of the researcher, many qualitative researchers give serious attention to the presence of the researcher in the research field and the researcher’s relationship with his/her research subjects.

Beginning in the 1970s, and increasingly since then, particularly in ethnographically oriented fieldwork, researchers began to question the position of the researcher as a neutral, objective outsider and suggest that, in order for any research field to be understood, the researcher would need to be reflexive about his/her “assumptions and biases” (Pillow, 2010, p. 272). Rather than being a source of contamination, the researcher’s own sociohistorical and political location then needs to be fully acknowledged (Rampton, 1992). In what became known as the “reflexive turn,” anthropologists and ethnographers in particular (see Clifford & Marcus, 1986; van Maanen, 1988) attempted to relocate the researcher as a presence in the research field and to allow the voice of the researcher to become part of the text. Linked to this was the “textual” turn, also influenced by postmodernism, in which the reports written by ethnographers and other qualitative researchers were seen to be constructed, rather than “true” representations of an observed reality. This view can be summed up by Geertz’s (1988) claim that “its [ethnography’s] epistemological foundations have been shaken by a general loss of faith in received stories about the nature of representation” (p. 135).

Schwandt (2001) defines reflexivity as “the processes of critical self-reflection on one’s biases, theoretical predispositions, preferences and so forth” that acknowledge that “the inquirer is part of the setting, context, and social phenomenon he or she seeks to understand . . . [and] can be a means for critically inspecting the entire research process” (p. 224). Schwandt further points out that reflexivity thus construed can be an “important procedure for establishing the *validity* [author emphasis] of accounts of social phenomena” (p. 224). He also alerts us to the extent to which researcher reflexivity can influence the nature and structure of the written account, leading to texts that are “messy” (Marcus, 1998), “forefront the politics of representation by making visible, through reflexivity, how we do the work

2 RESEARCHER REFLEXIVITY

of representation" (Pillow, 2003, p. 176), and may, therefore, challenge the more traditionally structured "*realist tale* [author emphasis] written by a detached observer" (Schwandt, 2001, p. 224).

As Pillow (2010) has pointed out, once researcher objectivity was open to question, the researcher's subjectivity was also open to scrutiny and "questions of how research relations and researcher subjectivity impact the doing of research became equally important" (p. 272). The reflexive turn, together with the influence of feminism, has led to greater scrutiny of power relations between the researcher and "the researched." Feminist methodologies have drawn our attention to how knowledge is generated, how it is reported, and how it is used, through a focus on the research process in its entirety from formulating research questions to gaining access, conducting interviews and observation, research relations, analyzing data, and the writing process (Pillow, 2010).

As summed up by Pillow (2010) "reflexivity has become an important tool" for demonstrating the qualitative researcher's "awareness of the problematic of doing research" (p. 274). Moreover, as she points out, it is often used to "potentially validate and legitimize research precisely by raising questions about the research process" (p. 274).

Cameron, Frazer, Harvey, Rampton, and Richardson (1992) in *Researching Language: Issues of Power and Method*, provide us with an early example of applied sociolinguistic work that directly confronts issues of the researcher's presence in the research field and is specifically reflexive as to the power relations between researcher and "researched" and the authority that researchers have to represent the identities of the research participants in their written accounts. The researchers, for example, decided to share with their research subjects the outcomes of their (the researchers') analyses of the data they had collected. Their scrutiny of both their research practices and their privileged location as researchers does not seem, however, to have had a significant impact on applied linguistic research. It could be argued that applied linguistics has, in the main, remained largely immune from the discussions around reflexivity that have occupied much debate and discussion on methodology in the social sciences from the 1980s onwards (see Talmy, 2010b). This should not surprise us, as Richards's (2009) state-of-the-art review of qualitative research in language teaching between 2000 and 2007 indicates that the proportion of papers that have a qualitative orientation published in leading journals is at most 25 per cent of the total number and only 10 percent in over half of the 15 journals surveyed.

Despite the broadening and strengthening of qualitative approaches identified by Richards (2009), it seems fair to say that there is less evidence of researchers taking an explicitly reflexive orientation to their research. A recent study by Talmy (2010a) of a school community in Hawaii gives us an idea of what "more reflexivity" in qualitative research might look like. He comments that TESOL as a field seems reluctant to talk about race and racism: "a great many TESOL studies have been conducted by raceless researchers working with color-neutral participants in contexts oddly devoid of any dimension of racial politics or history" (p. 39). He then goes on to explicitly situate himself in the research process as he talks about not only how he has represented the participants' racial identities in his writing but also about how he was racially identified by the students and compelled to reflect on his own privileged location as a "white" researcher. He also reveals how, in and through the interview process, he momentarily becomes complicit in the racist discourse of some of the students. He concludes by raising questions about how teachers and researchers could address discourses of race and racism in the classroom in an environment that is silent about race.

Within reflexive approaches, Macbeth (2001) identifies positional and textual reflexivity as two related epistemological strands. The former "takes up the analysts' (uncertain) position and positioning in the world he or she studies and is often expressed with a vigilance for unseen, privileged, or, worse, exploitative relationships between analyst and

the world" (p. 38). Textual reflexivity directly addresses "the work of writing representation" (p. 41) and calls into question the traditional social sciences' portrayal of "the disembodied voice of the modern analytic text" (p. 42). To date, these understandings of reflexivity can be seen most notably in applied linguistic and language teaching research in the increasing number of self-reflective and semi-autoethnographic accounts by language educators and academic researchers on their own language/academic discourse socialization (Casanave & Vandrick, 2003; Casanave & Li, 2008; Nunan & Choi, 2010). Morgan and Ramanathan (2005) note the growing use of "narrative/autobiographies to link personal experiences with sociohistorical and institutional power relations" (p. 156). Writing these reflexive narratives can be seen, as Kleinsasser (2000) puts it, as a way of "making the familiar strange," enabling researchers to "consider more deeply, ethical and epistemological tensions" (p. 158). Although, as Pennycook (2005) has argued, simply producing an account that uses the first person "I" may not necessarily "constitute in itself reflexivity" (p. 299) as the "I" or self performed may still be a unitary, essentialist self.

Vandrick's (2009) *Reflections of a Second Language Educator* is positionally reflexive in that she examines what she names "the colonial shadow" and the privilege accorded to her by her social class location and whiteness as she grows up with her missionary parents in postcolonial India. As she becomes a language educator, she considers how her privileged location has shaped and continues to shape her world and her work. At the same time, through her adoption of a hybrid format for her book, she produces a text that is consciously structured as unlike a "typical" academic work and that has an "embodied" author who locates herself in space and time and is present in her text.

In an article published in the "forum" section of *TESOL Quarterly*, Lin et al. (2004) critique "mainstream TESOL theoretical and research canons" (p. 495) for their adherence to positivist, decontextualized and ahistorical theories and methodologies that ignore the extent to which the field of TESOL has itself been shaped by race and gender resulting in a division of labor—a "gendered and racialized theory-practice divide" (p. 496)—that privileges and values certain types of theoretical research while devaluing more practice-oriented work often performed by women from minority groups. Each of the seven authors reflexively situates herself in terms of race, gender, ethnicity, and status and locates herself institutionally as positioned by these intersecting discourses. The authors, through their collective authorship, and a choice of format that intersperses personal narrative with theorized explanation, can be seen to be mounting a challenge to conventions of academic discourse that are elsewhere unreflectively adopted and can be understood as excluding of nontraditional voices.

Nelson (2005) directly engages with what she terms "the increasingly common practice of researchers writing their own subjectivity overtly into their research" (p. 315) in discussing aspects of an article she published earlier in *TESOL Quarterly* (Nelson, 1999) in which she addressed textual reflexivity through "crafting a text" in two parts—the first theoretically oriented and the second the presentation of a transcript into which she inserts (in italics) her own "moment-to-moment commentary as an observer" (p. 316). While in the original article she located her own positionality fairly subtly, in the reflexive 2005 piece she more overtly identifies her standpoint and invites her readers to consider experimenting with "ways of writing the researcher's intersubjectivity into a research text [that] can help to produce texts that do not so much transmit knowledge as illuminate and query the complex, uncertain processes of knowledge making" (p. 318).

There has, however, also been a reaction to texts that are considered to exhibit overly both positional and textual reflexivity. Canagarajah (2005) sees reflexivity in research and writing as "a fashionable gesture in certain disciplines now, treated almost as an end in itself" (p. 309), while Maton (2003) is dismissive of much positional reflexivity as narcissistic.

Reflexivity as methodological tool (Pillow, 2003) has had some impact in applied linguists'

returning to scrutinize earlier, unproblematized representations of the research process. While interviews are a widely used method in qualitative applied linguistics research, as Talmy (2010b) points out, little attention has been paid to the interview itself as a socially constructed communicative event, worthy of investigation in its own right. Richards (2009) comments that “analysis of interviews in our field [language teaching] still tends to treat them as reports rather than accounts, relying on unproblematized thematic analysis” (p. 160). In much applied linguistic research, interview data tend to be presented as realist, naturalized, and unproblematically “true.” Talmy (2010b) calls for

heightened reflexivity about the interview methods that applied linguistics researchers use in their studies, on the role of the interviewer in occasioning interview answers, on the subject “behind” the interviewee, on the status ascribed to interview data, and on how those data are analyzed and represented.

He notes that relatively few studies problematize the status and nature of the interview. Similarly, Canagarajah (1996) is critical of Peirce’s research on identity for not discussing how research subjects “negotiated subject positions with the researcher” (p. 328). Angélic-Carter (1997) however reflexively examined how, in an interview between herself and a student, power shifted between “interviewer” and “interviewee” as the topic shifted to one which the interviewee [the student] had much greater knowledge of than she did.

Coates and Thornborrow (1999) also problematize the notion that a transcript can be a “‘true’ version of a recording (audio or video) of spoken interaction” (p. 595). They set out to “challenge the assumption that there is such a thing as the perfect transcript” (p. 595), stressing that any transcription is always made on the basis of choices the linguist has made. They argue that data analysts have “failed to be frank” about this subjective dimension to transcription and attribute this to the “liberal humanist tradition in academia” (p. 596) that presents the researcher as an objective seeker after truth rather than as a reflective participant in the analytic process.

Ellwood (2006) revisits her doctoral work some years later and, while not problematizing her transcripts as such, interrogates her underlying assumptions through a close reexamination of seven minutes of her first interview with a Japanese student who “came out” to her in an interview. She scrutinizes the transcript as to her own positioning in and by discourses of heteronormativity and her positioning of the student through her interviewing practices. She frames her reanalysis in terms of a critique of conceptions of the notion of reflexivity itself as frequently used in educational research, concluding that while “researcher reflexivity is necessarily limited” (p. 81) as the researcher can never fully “know” their own subjectivity or its impact on their own research practices, “pursuing this sort of self knowledge is worthwhile nonetheless” (p. 82).

Ramanathan (2008) also returned to her doctoral research to critically revisit her ethnographic work on the discourses of patients suffering from Alzheimer’s. Drawing on the work of Derrida, she reexamines some of her transcripts to set up again a counter discourse to “psycholinguistic” discourses on Alzheimer’s. In a “confessional” paragraph which “disrupts” an otherwise fairly conventionally structured text, she describes how her initial attempts to do this were thwarted by her dissertation committee who rejected her approach as “too humanistic and not experimental enough” (p. 14), leading her to abandon this research and move into the field of ESL. Through Derrida’s lens she is led to question whether research is ever concluded; what the nature of “original” research is; the work of interpretation that the researcher does; and where meaning is located.

In a shorter piece that led to a series of responses in the *Journal of Language, Identity and Education*, Ramanathan (2005a) challenged an editorial decision to excise a passage in a journal article in which she explicitly discussed her positionality. The journal “forum” that

ensued is one of the first such discussions in an applied linguistics journal to foreground the concerns discussed thus far in this entry around reflexivity, positionality, representation, and textuality. In an accompanying piece (Ramanathan, 2005b), she presents the deleted text in which she discusses her social class position in Indian society, in its original context, and highlights the significance of this passage to both her theoretical arguments and the light it throws on her positioning as a privileged researcher, originally from India, now speaking “from the West.” Ramanathan and many of the other researchers whose work is discussed in this entry are experienced researchers, able to look back on earlier work and question and challenge. As Kleinsasser (2000) points out, however, writing reflexive texts that “blur distinctions between the personal and the theoretical” (p. 156), and in which the researcher acknowledges her multiple roles, can be risky for new researchers.

In an earlier piece, Canagarajah (1996) took issue with the standard research report writing genre being used by TESOL scholars for reporting on qualitative research, arguing that it embodied “the heady mood of positivism in the early days of empirical science . . . and served to maintain the pretense of objectivity, detachment, and neutrality, suppressing the agency of the researcher” (p. 323). He advocated the exploration of alternative modes of reporting that might include narrative, reveal process, be multivocal, dialogic, or collaborative (with participants). On the basis of the work discussed in this entry, the extent to which these sorts of reflexive texts are being produced in the field of applied linguistics more broadly appears limited and where they do appear, they are often shorter pieces in “forum” sections of academic journals. Alternatively, more narrative, autoethnographic pieces (often also shorter than traditional journal articles) have mostly been gathered in edited collections. Reflexive writing (and thus research that is reflexive) then seems caught between a rock and a hard place, reflexivity, both positional and textual, can be deemed irrelevant to the “real” research or a response to “fashion,” while too little, as in the case of the researcher whose comment was cited at the beginning of this entry, may be perceived as not enough. However, as Pillow (2003, 2010) argues, reflexivity should always be critical and as such continue to “trouble” and make “uncomfortable” all received versions of knowledge. Applied linguistics, in Pennycook’s (2005) words, “a constant catch up discipline . . . somewhat backward in its understanding of reflexivity” needs perhaps to give more consideration to researcher reflexivity to “push forward our thinking . . . in important ways” (p. 299).

Revernacularization and Revitalization of the Hebrew Language

BERNARD SPOLSKY

Like other “revived” languages such as Welsh and Breton (Jones, 1998), the modern variety of Hebrew is sufficiently different from earlier versions to lead Zuckerman (2006) to suggest it be renamed *Israeli*. The change that took place at the end of the 19th and the beginning of the 20th century was not in essence *revival*, which suggests restoration of an earlier form, but two different processes. The first, at the turn of the century, was *revernacularization* (Fishman, 1991b, p. 13), namely a change of priority from reading and writing Hebrew to speaking it, and the associated development of ways to communicate about daily life rather than religious matters and the sciences. The second, after 1920 when there were already fluent native speakers (Blanc, 1954), was *revitalization* (Spolsky, 1991)—the reestablishment of natural intergenerational transmission, as new parents who had learned the language in school began to speak it to their babies.

Regularly called a miracle, the double phenomenon depended on a unique combination of circumstances. One basic feature was the strong nationalist ideology that also led to many nonlinguistic changes, such as the willingness of East European Jews to immigrate to Ottoman Palestine, to switch from town to country life, and to adopt agriculture and physical labor as ideals. A second set of conditions concerned language choices. Once they had agreed to abandon the Yiddish they associated with the Diaspora and the coteritorial languages like Russian and Polish that they had spoken in Europe with non-Jewish neighbors, there was little if any motivation for the Zionists to choose the Turkish of Ottoman government officials and soldiers, the spoken Arabic of uneducated Palestinian peasants, or the Classical Arabic used by Islamic clergy. French too was dropped after the drying up of Rothschild support for their village schools, and German—the most common language of science at the time, and an appropriate medium for advanced education—was rejected for ideological reasons. Hebrew was left as the logical choice, its importance bolstered during the half-century from 1919 to 1948 that it served as a symbol of resisting British rule of Mandatory Palestine.

The process of establishing the status and form of modern Hebrew, drawing on nationalist theories (“one nation, one land, one language”) developed in 19th- and 20th-century Europe, and—taking advantage of the high status of Hebrew as a heritage language of religion and literacy—began in small farming villages in Ottoman Palestine where Jewish immigrants, most of them Yiddish-speaking, established schools in which the teachers were expected to use only Hebrew. Politically, it was an expression of Jewish territorial nationalism and a rejection of Diaspora languages, including the nonterritorial Jewish language, Yiddish (Fishman, 1991a).

During the last days of Ottoman rule, Hebrew spread to the new Zionist communal settlements (*kibbutzim*) whose settlers were even more radical in ideology and willingness to revolutionize their values, and it was soon established as the medium of instruction in most Jewish schools in the towns of Palestine, especially those conducted under the auspices of the *Hilfsverein der Deutschen Juden*, a philanthropic organization whose proposal to use German in tertiary science education was abandoned as a result of the 1913 “language

war" (Cohen, 1918), in which high school teachers and pupils demonstrated in favor of Hebrew.

After the end of the First World War, Hebrew was recognized by the League of Nations and the British Mandatory government of Palestine as the third official language, alongside English and Arabic, and became the language of instruction not just in Jewish primary and secondary schools but also in the first two tertiary institutions, the Hebrew University of Jerusalem and the Haifa Technion. An activist Hebraist campaign, with the motto "*Ivri, daber ivrit*" ("[you are] Hebrew, speak Hebrew"), spearheaded by the Legion for the Defense of the Hebrew Language (Shur, 2000), continued in the Jewish community until the establishment of the state of Israel in 1948 (Shohamy, 2007).

With the establishment of the state of Israel, two significant steps were taken. First, a government policy for state schools laid down that they should choose the language of the community; all Jewish schools were to continue to use Hebrew as the medium of instruction, and all Arab schools were to use Arabic (a policy that preceded a decision to require Arabic in Jordanian schools by some 15 years). Second, the British Mandatory government policy on official languages, established as English, Arabic, and Hebrew in 1920 by the King's Order-in-council, was amended by cancelling "any instruction in the Law requiring the use of the English language" (Rules of Government and Law, 1948, paragraph 15b), leaving Hebrew as the dominant major official language and Arabic as a nominal official language, and dropping English as the *de jure* official language while maintaining its *de facto* importance (Rubinstein (1986) notes, for example, that English translations of the laws regularly appear before Arabic).

In the years that followed, the masses of new immigrants were taught and urged to speak Hebrew. Bureaucrats, schools, and the army played major roles in support, so that by the 1960s, Hebrew was firmly established as the dominant hegemonic language. It was a different language from the earlier versions of Hebrew (biblical, mishnaic, medieval, and *haskalah* or enlightenment). It had been modernized to handle concepts of modern technology and education, although many speakers and writers preferred borrowed words to the official coinages of the academy of the Hebrew language. Originally with a Hebrew name, it has used the borrowed epithet *akademia* for many years.

It is to be heard on radio and television, in the street and the home, in workplaces and schools, and even on the football field (although obscenities are commonly borrowed from Arabic), as well as in the physics laboratory (Spolsky & Shohamy, 1999).

There continue to be oases of other languages in Israel: neighborhoods where *haredi* (ultra-orthodox) Jews use Yiddish, or recent settlers use Russian, French, Amharic, Spanish, or English (often with regular code-switching); and villages or large towns where Arabic is the vernacular. Earlier Jewish multilingualism is being replaced by Hebrew-English bilingualism, with English providing access to advanced education (Spolsky & Shohamy, 2001) and serving as the language of wider communication for tourism, commerce, information technology, and connections with Diaspora communities. In the absence of a language question in the Israeli census since 1980, changes in the sociolinguistic ecology are largely unstudied. Also, as a result of the political implications (Kuzar, 2001) of recognizing the lexical, grammatical, and phonological modifications that have taken place in modern Hebrew, there continues to be dispute about the extent to which the language is different from earlier versions, but its centrality to current issues of Jewish and Israeli ideology is clear (Stavans, 2008).

Reviving Irish From Independence to the Good Friday Peace Agreement

PEADAR Ó FLATHARTA

The New Irish State

This entry covers the period from the establishment of an Irish state in 1922 to the enactment of the British–Irish Agreement Act of 1999, when the Irish state agreed to restrict its sovereignty in Irish-language matters.

Part of the policy of the new Irish state established in 1922 was the revival of the Irish language as the language of public discourse. Although fully subscribing to this aim, it is unclear whether the leaders of the time fully understood the enormity of accomplishing such a task. The language spoken by a small percentage of people primarily in the west of Ireland was to be supported by a policy which can be summarized as follows: (a) the strengthening of the language in traditional language areas; (b) the revival of the language in all other areas through, primarily, the educational system; (c) a public administration system to promote the language; and (d) standardization and modernization of the language (Ó Riagáin, 1997). Such a policy would require a massive program of social and political change.

New Support Structures

The symbiotic relationship between the political movement and the supporters of cultural independence ensured a central place for Irish language in the new state. The Society for the Preservation of the Irish Language (Cumann Buan-Choimeáda na Gaeilge), founded in 1876, and Conradh na Gaeilge (the Gaelic League), founded in 1893, aimed at securing recognition for the language in Irish life and in particular in the educational system. The work of voluntary organizations focused on the importance of the language to the new state. The voluntary language sector established a key partnership role with the state apparatus. That relationship may be unique in national language planning systems.

The Irish language acquired an official status under the Constitution of 1922. The revised constitution of Ireland, *Bunreacht na hÉireann*, was adopted by the state in 1937. Article 8.1 of the constitution secures high status for the language as national and first official language of the state. The English language is recognized as another official language in Article 8.2.

Many of the language initiatives involved the Department of Education. In 1922 Irish became a compulsory subject in primary schools and in 1926 it became the medium of instruction in classes below second class. In the same year, *An Gúm* was established as part of the Department of Education and supported by a Terminology Committee to publish textbooks, dictionaries, and children's books in Irish. Irish became a compulsory subject for the secondary school Intermediate Examination in 1928, and for the secondary school Leaving Certificate in 1934. In 1946 grants were given to schools for excellence in Irish, and in 1958 rules to standardize grammar and spelling were adopted.

Outside schools:

- in 1928 Taibhdhearc na Gaillimhe (the Irish Language National Theatre in the city of Galway) obtained its first annual subsidy;
- in 1927 Irish became a compulsory subject for entry into the civil service;
- the 1929 University College Galway Act obliged the University to provide courses in Irish and to employ bilingual staff;
- in 1940 the School of Celtic Studies was instituted as part of the Dublin Institute for Advanced Studies for research and as an academic publisher; and
- the Linguistic Institute of Ireland was established in 1967 and undertook many research projects in linguistics until its closure in 2003.

Support for non-state initiatives was also channeled through the Department of Education, and by the 1940s there was a myriad of organizations supported by state monies. To avoid duplication the government sanctioned the establishment of Comhdháil Náisiúnta na Gaeilge, a coordinating body for non-state organizations, in 1943.

A Government Department for the Gaeltacht

Gaeltacht (Irish-speaking) areas, geographically isolated and underdeveloped, primarily on the west coast, were defined following the Gaeltacht Commission Report of 1926, and were viewed as the source of language learning and support to add to the level of proficiency in the wider national community. The growth of English as the language of public and civic administration, however, threatened the linguistic integrity of the Gaeltacht areas. A report by Comhdháil Náisiúnta na Gaeilge in 1945 stated that 75–90% of church, government, local government, trade, transport, sport, and recreation affairs were in the English language only in Gaeltacht areas. A government department, Roinn na Gaeltachta (the Department of the Gaeltacht), was established in 1956 and it in turn administered Gaeltacht housing grants schemes since 1929, the 1934 scheme for Gaeltacht service industries to assist industries, and a 1952 scheme to subsidize the publishing of Irish-language books.

Economic Development in the Gaeltacht

A semi-state body charged with the economic development of the Gaeltacht, Gaeltarra Éireann, was established in 1957 under the aegis of the Department of the Gaeltacht. Údarás na Gaeltachta (the Gaeltacht Authority) was established in 1980 to replace Gaeltarra Éireann. The organization did not, however, enjoy full authority over Gaeltacht regions. Its remit was limited to economic, social, and cultural development, and the majority of the board of the authority was to be democratically elected by the people of the Gaeltacht every five years. The Údarás was established following a campaign for Gaeltacht rights. The new body continued the model of economic development developed by its predecessor, Gaeltarra Éireann, and proved successful in attracting inward investment. This investment creates valuable employment for the Gaeltacht communities. Údarás has been criticized for not paying due attention to securing the future of the language, for not developing a more holistic model of entrepreneurship, and for failing to halt the decline of the traditional language community. Some claim that the development policies have contributed to the decline of the language by strengthening the perceived higher status of English English in the boardrooms and Irish on the factory floor.

Arts and Media

In 1926 Raidió Éireann (the national broadcaster) came on air with a quota of programs in Irish. A separate national radio station, Raidió na Gaeltachta, was established in 1972, Raidió na Life (independent Dublin station) in 1993, and the TG4 television station in 1996.

The policy of creating literature and reading material in the language focused in the beginning on translating recognized authors, primarily from English, but later a substantial body of literature in Irish was produced by Máirtín Ó Cadhain, Máirtín Ó Direáin, Seán Ó Riordáin, and others. An average of 200 books in the language are published yearly, with a weekly newspaper, periodicals, and other developments in the electronic media. Traditional arts flourished in the period.

Change of Policy

A substantial policy change occurred in the 1960s, with the state now aiming at preserving the language in a bilingual society (Ó Murchú, 1970). This resulted in the weakening of the position of the language in civil and public administration. In 1973 Irish was withdrawn as a compulsory subject in the Leaving Certificate, and Ireland did not seek official working language status for the Irish language upon accession to the European Union. In 1974 the requirement of competency in Irish for employment in the civil service was abolished.

A state body, Bord na Gaeilge (the Board for Irish), was established in 1978 with a coordinating and promotional role. The Bord focused on influencing primarily at state level, while its statutory functions were limited to advice and consultation.

Parents were key players in a new movement to set up preschool and Irish-medium schools, Gaelscoileanna. Growth in this area has resulted in about 6% of the annual school cohort getting their education through the medium of Irish. An Chomhairle um Oideachas Gaeltachta agus Gaelscolaíochta (COGG) (the Council for Gaeltacht and Irish-Medium Education) was established in 1998, with teachers, parents, and other education experts serving on the board, and charged with advising the Minister for Education, coordinating the provision of textbooks and educational materials, and commissioning research projects.

Reviving Māori

TONY TRINICK

The health of *te reo Māori* 'the Māori language' in New Zealand was significantly compromised throughout the course of the 20th century, with language loss accelerating post-World War II (Benton, 1991a). In 1930, a survey of Māori children estimated that 96.6% spoke only Māori at home. By 1960, only 26% spoke Māori (May, 2010). After nearly two centuries of contact with Europeans, the Māori language was, by the 1960s, endangered (Benton, 1991b), threatened with possible extinction (Spolsky, 2003).

The perilous state of the Māori language was highlighted by key studies in the 1970s (Benton, 1991b) and a subsequent Treaty of Waitangi claim (Waitangi Tribunal, 1986). The 1986 claim to the Waitangi Tribunal sought to have Māori recognized as a *taonga* 'treasure' and therefore guaranteed government protection under the 1840 Treaty of Waitangi signed between Māori and the (British) Crown (Orange, 1987). The Tribunal found in support of the claimants, and its subsequent recommendations to the government of the day led directly to the passing of the Māori Language Act (1987), which declared Māori to be an official language of New Zealand, and the establishment of Te Taura Whiri i te Reo Māori (Māori Language Commission; Harlow, 1993). These decisions accorded *te reo Māori* for the first time since colonization an official language status within Aotearoa/New Zealand, but with significant limits (May, 2003). For example, the Language Act did not extend the right to use or to demand the use of Māori in the public domain beyond the oral use of the language in courts of law and some quasi-legal tribunals (Spolsky, 2003).

In response to the endangered state of the Māori language, Māori groups and communities developed a range of grassroots education initiatives to revitalize, expand, and modernize the Māori language. These groups included early childhood (Te Kōhanga Reo; see King, 2001), primary school (Kura Kaupapa Māori; see Smith, 1990), secondary education (Wharekura; see Campbell & Stuart, 2009), adult education programs (Te Ātaarangi community-based group; see Spolsky, 1989), and tertiary institutions (Te Wānanga o Raukawa; see Royal, 2007).

Māori language planning has been largely reactive and has proceeded very much on an ad hoc basis without the cohesive force of an explicit and overriding policy (Harlow, 2003). Language planning can be seen as a body of ideas, laws, and regulations (language policy) beliefs and practices intended to achieve a planned change in language use in one or more communities (Kaplan & Baldauf, 1997). Although it may involve government action, a great deal of language planning occurs in a range of social contexts and at different levels (Spolsky, 2004). Researchers in language planning have attempted to differentiate three distinct kinds of activities: those concerned with attempts to modernize the language (corpus planning), those concerned with modifying the environment in which a language is used (status planning; Haugen, 1983; Kaplan & Baldauf, 1997), and acquisition planning, with a particular focus on its implementation in education (Cooper, 1989).

Corpus planning focuses on changes by deliberate planning to the actual corpus or shape of a language (Antia, 2000). This may be achieved by creating new words or expressions, modifying old ones, or selecting among alternative forms (Kaplan & Baldauf, 1997) and is often related to the standardization of a language (Clyne, 1997). The Māori language has had a standard orthography for some time (Harlow, 2003); however, the language has

changed and developed greatly over the last two hundred years by borrowing words, modifying the meaning of existing ones, and creatively developing new ones. These changes have occurred for functional reasons over time without any specific language plan or policy (Keegan, 2005). Until the 1980s, the predominant process of creating new Māori words was to “borrow” English or in limited cases French words (Benton, 1991a).

Subsequent to the 1980s, the methodology was to avoid the use of borrowings from English but rather to look to classical sources for roots or create new words altogether (Barton, Fairhall, & Trinick, 1998; Keegan, 2005). In this regard, Māori is unique among the Polynesian languages of the Pacific (Trinick, 2010). Since the 1980s, there has been a very rapid expansion of *te reo Māori* vocabulary and the codification of the language, spearheaded by Taura Whiri i te Reo Māori, to keep up with language expansion demand from Māori-medium schools (Barton et al., 1998) and from government departments and businesses (Keegan, 2005). In many language development situations, the development of new vocabulary is rather incidental (Spolsky, 2004). But for Māori, the vocabulary needs have been great enough that committees and institutions like Te Taura Whiri have been set up to manage the process (Harlow, 1993). Despite the range of institutions, no centrally agreed body has emerged which is able to plan, coordinate, and define Māori language policy. As a consequence, Māori language planning continues on a disjointed basis (Harlow, 2003).

Status planning refers to deliberate efforts to allocate the functions of languages and literacies within a speech community (Kaplan & Baldauf, 1997). Status planning involves decisions a society or group must make about the language selection and implementation (Ridge, 1996). In New Zealand, these decisions are frequently driven by European attitudes to Māori (Boyce, 2005) and wider issues of human rights (May, 2000). The attitudes that the New Zealand population, particularly the majority European population, have to the Māori language were an important influence on the loss of the language in the first instance (Boyce, 2005), and can be a direct impediment to Māori language regeneration initiatives in the present (May, 2000). Research has consistently shown that the attitudes of non-Māori New Zealanders to the Māori language are considerably less positive than those within the Māori community (Nicholson & Garland, 1991; Te Puni Kōkiri, 2002, Harlow, 2005). This requires special language planning that targets the attitudes and behaviors of majority language speakers, or “planning for tolerability” (de Bres, 2008). For Māori to survive, it requires positive attitudes from both non-Māori and Māori, which ideally foster beneficial language behaviors (Boyce, 2005).

Corpus planning and status planning are often manifested in explicit language policies at government and local levels (Spolsky, 2003). It is argued that New Zealand has never had a comprehensive language policy at higher levels of government (Peddie, 2005) and planning and policy tended to proceed on an ad hoc basis (Kaplan, 1994; Peddie, 2005). However, there have been attempts to develop policies that relate to the Māori language. The first comprehensive Māori language policy was initiated by Taura Whiri i te Reo Māori to ensure not only that Māori was to be the principal language of a significant number of people in Māori domains, to be spoken by different generations and accepted in non-Māori domains, but also the development of positive attitudes (Spolsky, 2003). A range of subsequent policies was developed by various government departments, essentially with the same goals (Te Puni Kōkiri, 1999, 2003).

Although a component of the broader national language planning initiatives, education has been possibly better supported by government agencies and Māori communities. For language in education planning, the New Zealand Education Act (1989) and the Te Aho Matua Amendment Act (1999) are central. These acts and subsequent Māori-medium curriculum guidelines developed by the Ministry of Education legitimized teaching in the medium of Māori (not just Māori as a subject) for the first time since the late 1800s (McMurchy-Pilkington, 2004).

There is concern about the direction and focus of language planning and policy development with regard to the Māori language. Issues have arisen as to the somewhat ad hoc nature of the corpus development (Keegan, 2005), the dominant language ideology of purism (Harlow, 1993), and possible effects on Māori culture as a consequence of language change (Barton et al., 1998). Much of Māori language policy has focused on education. It is argued that education alone is not sufficient to reverse language shift, and that homes and communities have a major role to play in language continuation (Chrisp, 2005). Also, Māori has not been promoted enough by the government for the language to have a sufficiently good image (Nicolson, 1997). As a result, the number of fluent Māori speakers continues to diminish.

So What Is the Future?

According to Māori language surveys in 2001 and 2006, the decline in the number of Māori language speakers has been halted (Te Puni Kōkiri, 2003, 2007). However, the Māori language is still in a precarious state and requires continued strategic planning and policy to ensure its survival as a modern, vibrant language appreciated by Māori and non-Māori alike.

Rhetorical Discourse Analysis

JENNIFER ANDRUS

Introduction

Rhetorical discourse analysis (RDA) brings together methods and theories from strands of discourse analysis (DA), classical rhetoric, and rhetorical analysis. As I will show in what follows, rhetoric and DA share a common object, discourse, and some of the same concerns and concepts, such as interaction, context, style, and effect. The overlapping concerns create spaces where theories and methods can be brought together to add depth and nuance to analysis. The goal of much of the scholarship that uses an RDA framework is to better understand communication in context. As Tracy (2003) puts it: “rhetorical criticism and discourse analysis share the commitment to the close study of texts in contexts” (p. 727). In fact, van Dijk (1985) suggests that key people in the rhetorical tradition (Aristotle, among others) were the original discourse analysts. Johnstone (2008) argues that “rhetorical study has always involved discourse analysis, explicit or not, as rhetoricians have analyzed relatively self-conscious, public, strategically designed talk and writing to see what makes it work” (p. 7). Unsurprisingly, then, DA and rhetoric share some common assumptions, for example, that “discourses shape the world, and discourse is shaped by the world” (Eisenhart & Johnstone, 2008, p. 11), linguistic and stylistic choices are strategic, and rhetorical issues like ethics and civic engagement are enacted discursively. In other words, DA and rhetoric come together around the common view that language, whether spoken or written, does something in addition to or beyond merely reflecting the world as it is. DA and rhetoric also share a core interest in the particulars of discourse and communication. The association between the projects of DA and rhetoric create a space of cross-fertilization out of which a new theory of discursive action is emerging.

Though they have much in common, the fields of rhetoric and DA highlight different discursive processes, aspects of discourse, or both. In other words, the two fields have similar interests, but different ways of analyzing and talking about those interests, which allows them to be used together to attend to what Huckin (2002) calls “different levels of granularity” (p. 159). One way of thinking about the difference between the two fields is in terms of micro and macro (see Eisenhart & Johnstone, 2008). DA is oriented toward microprocesses: the linguistic details in stretches of spoken and written discourse (see Johnstone, 2008). Rhetoric is oriented toward macroprocesses: speaker authority, audience response, persuasion and other effects of texts, the rhetor’s goals, contextually situated interaction, and the like. As it is described by scholars like Huckin (2002), Barton (2002a, 2002b), and Eisenhart and Johnstone (2008), DA is productively paired with rhetoric, because it is a context-sensitive, qualitative method that allows for a systematic, data-based, inductive approach to the analysis of texts and interaction. On the other hand, rhetoric offers discourse analysts tools for theorizing persuasion, authority, asymmetrical power relationships, and political activity. I should note that critical discourse analysis (CDA) is also concerned with macrolevel functions and asymmetrical relationships and politics, and it is certainly common for scholars to combine CDA with RDA (see Huckin, 2002; Cramer, 2008; Stewart, 2008; Andrus, 2011). DA and rhetoric also intersect in social psychology and

pragmatics, but because that work falls outside of the specific aims of this entry, I will not detail those relationships. It is the goal of this entry to distinguish RDA from other forms of DA, describe its analytical benefits, and review current RDA scholarship. I will first give some background on the fields of rhetoric and DA.

The Tradition of Rhetoric

Traditionally, rhetoric traffics in local, discursively contingent probability rather than universal, abstract truth, which led to its rejection from the philosophies of Plato and Socrates. Rhetoric has been described as “an alibi for eccentricities, for interdisciplinarity and the violation of disciplinary boundaries, and for the development of alternate intellectual strategies and rogue practices” (Charland, 2003, p. 121). As such, rhetoric can be many things: a method of invention, a critical project, or committed to civic/political action (Charland, 2003). Because it is a sort of disciplinary chameleon, rhetoric is open to innovation and recombination with academic areas like DA. Chameleon though it may be, at the center of most approaches to rhetoric is an interest in the relationship between discourse and context (Bitzer, 1968; Vatz, 1973; Aristotle, 1991), in the stylistic details of discourse, or rhetorical figures, and in the contextual use of those figures to persuade a particular audience (Aristotle, 1991) or to create “identification” between the rhetor and the audience (Burke, 1950). The field of rhetoric is also concerned with civic action and the discourse of those in power (Huckin, 2002), leading Glenn (1997) to contend “rhetoric always inscribes the relation of language and power at a particular moment (including who may speak, who may listen or who will agree to listen, and what can be said)” (pp. 1–2). Rhetoric is thus concerned with the details that facilitate communication and persuasion, with some scholars particularly interested in the role power plays in the interaction.

Discourse Analysis

DA distinguishes itself from linguistics by analyzing discourse, or language in action (Johnstone, 2008). As Johnstone puts it, “calling what we do ‘discourse analysis’ rather than ‘language analysis’ underscores the fact that we are not centrally focused on language as an abstract system” (p. 3). Similarly, Gee (2005) calls DA a method and theory for understanding how language gets used in context “to enact specific social activities and social identities” (p. 1). The aim of DA is to study larger linguistic structures, “chunks of information across a series of sentences,” paragraphs, or texts (Johnstone, 2008, p. 6). Some scholars pair this view of discourse with a Foucauldian one (Discourse), looking for the ways that actually occurring discourse reproduces and circulates ideological structures that constrain and enable discursive choices and subjectivity (see Stygall, 2001; Gee, 2005). A scholar might consider DA to be “what they do, how they do it, or both” (Johnstone, 2008, p. 1). In other words, DA is sometimes an analytical framework at work in every level of a project, and it is sometimes more instrumental, a set of methods that can be imported into a project as needed. With the analytical attention on language in use and in longer stretches, DA is useful for the kinds of analytical projects that are completed in rhetoric.

Rhetorical Discourse Analysis

According to Barton and Stygall (2002), rhetoricians have been using DA methods for years, and likewise, linguists have occasionally pulled concepts from the rhetorical tradition. The label “RDA” is fairly new, with only a few scholars such as Arribas-Ayllon, Sarangi,

and Clarke (2009) explicitly using the label. They pair DA, which “focuses on the pragmatic, functional and contextual use of language to accomplish interactional objectives and organize social activities,” with rhetoric, because of rhetoric’s traditional “focus on the *persuasive* dimension of language use” (p. 175, emphasis in original). Thus, RDA allows them to understand how and why a text is persuasive. Gill and Whedbee (1997) also note rhetoric’s long concern with persuasion and influence, as does Wooffitt (2005), who included a chapter called “Persuasion and Authority,” in her book on conversation analysis (CA) and DA. RDA is thus oriented toward a view of language as rhetorical, persuasive, and constitutive, rather than neutral and reflective.

The collection *Rhetoric in Detail*, edited by Johnstone and Eisenhart (2008), is also aimed at both rhetoric and DA audiences, with many of the projects operationalizing an RDA framework—doing fine-grained analyses of typically rhetorical objects. In their introduction, Eisenhart and Johnstone (2008) argue that the combination of rhetoric with DA allows the rhetorical critic to proceed empirically, locating linguistic features in discourse and analyzing and explaining them using a combination of methods and theories. The articles in the book exemplify this claim, examining topics such as cold war refugees, bureaucratic style, arts controversies, educational chat, deafness, humor, scientific discourses on sexuality, futurity in political discourse, rhetorical agency, and the South African Truth and Reconciliation Commission. Other topics analyzed within an RDA framework are composition (Huckin, 2002; Mayes, 2010), disability studies (Barton, 2007), everyday talk (Tracy, 2002), media discourses (Cramer, 2008), medical discourses (Lay, 2002; Scollon, 2006; Arribas-Ayllon et al., 2009), legal discourses (Stygall, 2001; Andrus, 2011), political discourses (Huckin, 2002), refugees and transnational flows (Hanson-Easey & Augoustinos, 2010), and technical discourse (Friess, 2010). The remaining sections go into more detail about current work using RDA.

Rhetorical Discourse Analysis in Rhetorical Criticism

Johnstone (2008) argues that “rhetorical study has always involved discourse analysis, explicitly or not, as rhetoricians have analyzed relatively self-conscious, public, strategically designed talk and writing to see what makes it work” (p. 7). DA supplements rhetorical analysis by borrowing methods and theories from sociolinguistics, and other schools of linguistics, to collect, analyze, and explain such discourses. For example, Ahram (2008) uses Geertz’s concepts of framing and footing with rhetorical analysis to understand identity construction in the Sunni Islamist movement in Iraq over the last five years. Huckin (2002) uses an RDA approach to interrogate a “discourse of condescension” established in letters between legislators and citizens, and Dunmire (2005) looks at the intersection between future tense and ideology in political discourse. Other work on political discourses focuses on refugees and transnational flows. For example, Hanson-Easey and Augoustinos (2010) examine Australian policies regarding Sudanese refugees. Still other work that draws from rhetoric and DA analyzes the intersection of discourses on sexuality, media, and the popularization of science (see Stewart, 2008). Some scholars add corpus linguistics to the mix to analyze, for example, the metonymic construction of “public” in deliberative democracy (Cramer, 2008). Concerned with the rhetorical force of legal discourses, Stygall (2001) uses RDA to understand the role of expert witnesses in trials, and Andrus (2011) analyzes trial and appellate discourses that constrain witnesses’ narratives.

The collaboration between rhetoric and DA has facilitated recent rhetorical research of unplanned, spoken discourse, that is, interviews and “natural” or “spontaneous” talk, in a range of contexts. For example, Barton’s work on disability narratives told by individuals with disabilities and legal professionals (2007), Lay’s work on discourses of

midwifery (2000), Bhasin's work on humor and Indian identity (2008), and Tracy's work on identity construction in everyday talk (2002) analyze transcripts of ethnographically collected, spoken discourse.

Rhetorical Discourse Analysis and Rhetoric/Composition

The rhetoric/composition community also uses both ethnographic methods and RDA in classroom and pedagogy research. In their collection *Discourse Studies in Composition* (2002), Barton and Stygall explain that DA "offer[s] composition scholars methods of research that provide insight into the linguistic aspects of writing" (p. 2). To this end, they include work by linguists. As a context-sensitive, qualitative method, DA has been well used in composition studies, primarily to analyze classroom interaction, student writing, pedagogical style, and first-year writing programs (see Mayes, 2010), among other things.

Rhetorical Discourse Analysis in the Study of Language Structure and Use

It is arguably most common for linguists to use "rhetoric" or "rhetorical" in the non-academic sense of the word, to loosely mean persuasive language or language that is all style with no substance. When DA scholars use the term more technically, referencing the academic field of rhetoric, they tend to take an Aristotelian approach. This work focuses on the appeals (ethos, pathos, logos), rhetorical topoi, tropes, and figures (metonymy, metaphor, anaphora, etc.). For example, Johnstone (2009) uses the concept of ethos to explain how a speaker can create an enduring linguistic style. Biber, Connor, and Upton (2007) identify "rhetorical appeals analysis," which is based on the Aristotelian appeals, ethos, pathos, and logos, as a method of "bottom-up" DA. Gill and Whedbee's (1997) detailed description of rhetoric for discourse analysts focuses on persuasion and traditional concepts such as genre, context, credibility of the speaker, style, timing, and so forth.

Deviating somewhat from this model, Scollon (2006) applies Kenneth Burke's mid-20th-century approach to rhetoric in a (C)DA framework. This work is aimed at understanding the motives of a speaker or writer rather than the stylistic features of a discourse. Wooffitt (2005) also develops a broader view of rhetoric as constitutive, which she uses to find common ground between CA and DA.

Conclusion

The relationship between DA and rhetoric is typically one of borrowing—pulling in a single theory and method, or a set of them, out of one field into the other to enhance the analysis in some way. As more and more scholars combine these two fields, RDA is becoming an analytical framework in its own right. This is a promising development, because RDA provides a robust set of tools that allow the analyst to look at the micro and macro dimensions of different kinds of communication in order to understand the ways in which communication is situated, intertextual, and an ongoing activity. RDA also facilitates interdisciplinary research and interaction and allows for detailed, nuanced, and deep analyses, because it takes into account and responds to issues and concerns from multiple fields and disciplines. Taking into account more than one set of assumptions leads to careful work that pays attention to detail without losing sight of the bigger picture, as well as work concerned with the big picture that does not lose sight of the details.

Rhythm and Timing in Interaction

BEATRICE SZCZEPEK REED

The analysis of spontaneous discourse highlights an aspect of language that often remains unnoticed in other, more theoretically minded fields of linguistics: the emergence of language through real time. While it is possible to study language by analyzing de-contextualized words and sentences, the role of language for human interaction can only be fully appreciated by studying how specific speakers use specific types of utterances at specific points in conversation. Any point in conversation is fundamentally defined by the utterances that precede it; and those that follow it. Many analysts of discourse therefore refer to this aspect of utterances as their “sequential location,” that is, their position within and in relation to an emerging sequence of conversational events. However, the term “location” is a slight misnomer. What is referred to is, of course, not a place, but a moment in time. It is for this most fundamental feature of conversational language as unfolding through time that rhythm and timing are of crucial significance for an understanding of natural, spontaneous discourse.

It has been claimed that participants in naturally occurring English conversation routinely orient to a notion of “one party talks at a time” (Sacks, Schegloff, & Jefferson, 1974, p. 700). Although this assertion has been strongly criticized, particularly from a cross-cultural perspective, it does seem that even in interactions in which several participants speak simultaneously for lengthy periods, those participants orient to a notion of taking turns at speaking. In doing so, they show with each utterance they produce that they are in some way reacting to, or following up on, a previous utterance—either their own, or another speaker’s. This perspective on language as emerging through time has led to a description of speaker changes as conversational “turn-taking” (Sacks et al., 1974), and coherent strings of turns as conversational “sequences” (Schegloff, 2007). Detailed analysis of spontaneous discourse has revealed, first, that speakers are extremely precise in their timing of next turns, and in their organization of talk into sequences; and second, that timing and rhythm play a fundamental role in the collaborative interactional process that is spontaneous conversation. Below are outlined some of the main implications of timing and rhythm for natural interaction.

Regarding the *timing* of next turns, analysts of discourse have long since noted the conversational significance of *when exactly* speakers produce their turns. Keeping in mind the sequentially emerging nature of interaction as described above, any turn is also a *next* turn (possibly with the exception of the turns that initiate interactions, such as first greetings). This status of turns as next turns means that we can describe their timing in relation to prior turns. An initial finding by early conversation analysts was the impressive accomplishment by conversational participants to produce next turns precisely at the moment at which previous speakers have stopped speaking. This feature of conversational turn-taking has been termed “precision timing” (Jefferson, 1973). It means that in the default case, next turns by next speakers are neither delayed by lengthy pauses nor produced too early, causing extensive overlapping speech. This ability to produce next turns so precisely in next position does not mean that pauses and overlapping speech are rare; however, it does mean that they are either very brief, or treated as potentially nonroutine by the conversational participants themselves, at least in many standard varieties of British and American English.

The ability of conversational participants to time their next turn onsets exactly to previous speakers' turn completion points has led many analysts of discourse to investigate the predictability of language, and of turns-at-talk, particularly in English. The argument underlying this interest assumes that, given the cognitive effort involved in planning and the starting up of a next turn, it would be impossible for speakers to begin speaking so soon, that is without any pausing at all, if they had to wait for another speaker's utterance to be fully completed. And indeed, research on Dutch and German conversational language has found that a combination of word choice and syntax allows listeners to predict, sometimes relatively early on in the sentence, how and when a sentence is going to end (Auer, 1996; de Ruiter, Mitterer, & Enfield, 2006; Magyari & de Ruiter, 2008). Research on English conversations has found that intonation and rhythm help project on a more local level, that is less far into the future than lexis and syntax, when exactly a current turn may be completed (Grosjean, 1983; Couper-Kuhlen, 1991; Grosjean & Hirt, 1996; Schegloff, 1998; Wells & Macfarlane, 1998; Auer, Couper-Kuhlen, & Müller, 1999).

The routine nature of very precise next-turn timing means that by placing a next turn at exactly the moment at which a previous speaker has finished, a next speaker can show that their turn is default, not only in terms of its timing, but also in terms of the conversational action it is designed to accomplish. However, it would be wrong to suggest that the placement of next turns with no gap and no overlap is necessarily the preferred case; or that any next turn that deviates from this rule signals some sort of interactional problem. Close analysis of natural conversation shows that this interpretation would be too simplistic. Compare, for example, an invitation, followed by an acceptance of the invitation by the addressee: Were the acceptance to be delivered with no pause whatsoever, this could signify a routine sequential development, both in terms of its timing and its conversational implications. Were the acceptance of the invitation to be delayed, this may give cause for an interpretation of a nonroutine, and possibly dispreferred, development. Were the acceptance to be delivered slightly early, creating a small amount of overlap, this could be a particularly enthusiastic acceptance, and possibly the most preferred option. As this example shows, the three variations of timing—early, on time, or late—can have a significant impact on the interactional status of a next turn, and a strong influence on the subsequent development of the conversational sequence.

An even more frequently occurring example of early turn onset that nevertheless accomplishes a routine conversational action is the case of so-called "terminal overlap" (Jefferson, 1984). If we adopted an overly simplistic view of timing in conversation, turns that occur before a current speaker has finished speaking may be termed "interruptions." However, not all interruptions are illegitimate conversational actions, that is instances of speakers grabbing the floor when others are still in the middle of an ongoing utterance. Some early next turns occur because their speakers have predicted an upcoming turn completion in the immediate future, and have started speaking although the currently speaking participant has not entirely finished. Such terminal overlap typically involves no more than a single word of overlapping speech, and is not treated by participants themselves as problematic. Furthermore, some next turns are placed early, that is at noncompletion points, precisely because they are not designed as turns in themselves, but are instead designed as supporting a current speaker in their right to hold the floor (French & Local, 1983). For example, agreeing next turns such as "yeah that's right," or response tokens such as "mhm" are frequently produced when current speakers have not yet finished. Instead of being instances of problematic early timing, they are instead placed very precisely at moments during currently ongoing turns where such responses are made expectable by the unfolding interaction.

Instances of late timing, that is next turns which are placed after a short pause, can indicate a next speaker's delay, and as such signal interactional difficulties, as, for example,

in our above example of a delayed response to an invitation. However, gaps between speakers can also indicate unproblematic next turn onsets. This is the case in some instances in which speakers adhere very precisely to *speech rhythm*.

It is not at all surprising that speech is produced in a rhythmic manner: After all, many physical activities, such as breathing or walking, are done with great regularity. For unimpaired speech, humans also follow a broadly rhythmic pattern. However, the way in which speech rhythm is organized varies from language to language. Phoneticians have classified the languages of the world into two rhythm classes: stress-timing and syllable-timing (Pike, 1945; Abercrombie, 1967). Put very simply, stress-timing involves the perception of all stressed syllables as being placed on regular rhythmic beats; whereas syllable-timing involves a perception of each syllable as a rhythmic beat in itself. Since this original classification, research has shown that few languages fall entirely into one of these two categories; instead, languages are considered as being situated along a spectrum, and phoneticians speak of languages with a tendency toward either of the two classes (Dauer, 1983; Miller, 1984; Laver, 1994). English, particularly British English, has been described as having a strong tendency toward stress-timed speech rhythm. In a stress-timed language, every stressed syllable is perceived as a regular beat. This, however, does not mean that one would be able to set a metronome against an English speaker's speech and find the stressed syllables distributed across a perfectly isochronous rhythm. Instead, speech rhythm is very much a perceptive phenomenon. The human ear perceives stressed syllables in stress-timed languages as regular, even if their placement deviates to a certain degree from precise regularity.

Speech rhythm is most easily detected in read-aloud speech, where speakers' fluency is not hindered by the cognitive planning process that is required for spontaneous speech production. However, natural conversation, too, displays rhythmic organization. In fact, research by Erickson (1992) shows that not only speech, but also other actions, such as handling cutlery during a meal, are placed according to regular rhythmic beats. Returning to the above issue of turn-taking, rhythm has been discovered to be highly relevant for the negotiation over who speaks next in conversation. This has been revealed in research carried out primarily by Elizabeth Couper-Kuhlen (Couper-Kuhlen, 1991; Couper-Kuhlen & Auer, 1991; Couper-Kuhlen, 1993; Auer & Couper-Kuhlen, 1994; Auer, Couper-Kuhlen, & Müller 1999), who showed that, in English, conversationalists continue a previous speaker's rhythm in their immediately following turn. Couper-Kuhlen discovered that in instances of smooth turn-taking, next speakers produce the first stressed syllable of their turn precisely when the previous speaker's turn would have projected a next rhythmic beat. She shows that those turns that are "in time" with previous turns are the default case; whereas turns that are early or late, according to a previously established rhythmic pattern, are frequently also cases of turns that are otherwise interactionally problematic.

As Couper-Kuhlen shows, this finding allows for a new perspective on gaps between turns. While smooth turn-taking typically involves only minimal pausing between speakers, so-called "latching," that is the immediate startup of a next turn without even the slightest gap, is in fact rare. In reality, precise measurement of pauses in between turns shows that while we may notice some pauses in a given context, in a different context we may not notice a pause of exactly the same length. Couper-Kuhlen's finding of turn-transitional speech rhythm provides the answer for this discrepancy. In order to place their first stressed syllable on the next rhythmic beat as projected by a previous speaker's rhythm, next speakers may sometimes be required to leave a small gap between the two turns. If, for example, a first turn ends with a stressed syllable, and is not followed by any unstressed syllables; and if the next turn begins with a stressed syllable, and is not preceded by any unstressed syllables; then the speaker of the second turn will have to leave a gap the length of the rhythmic interval in order to place their next turn on the next rhythmic beat. This kind of

4 RHYTHM AND TIMING IN INTERACTION

gap would not be very noticeable to listeners or participants themselves, as it would be part of the rhythmic organization of conversation. However, a gap of the same duration may be noticeable in another context, in which the rhythmic integration of a next turn requires an earlier placement of the first stressed syllable.

Later research showed that this kind of timing is used by conversational participants in order to design their talk as continuing a prior speaker's sequence, or as beginning a new sequence (Szczeppek Reed, 2009). While new conversational sequences are typically begun after a noticeable gap between turns, continuations of sequences routinely involve rhythmic integration of the continuing turn.

Speech rhythm in discourse has also been found to have crosscultural implications. More generally, it has been identified by applied linguists to be a feature of speech that affects non-native English pronunciation (Adams, 1979; Taylor, 1981; Bond & Fokes, 1985; Brown, 1988), particularly if a learner's native language has a tendency toward syllable-timing, rather than stress-timing. The main influence of a syllable-timed rhythm on a stress-timed language is on the pronunciation of "weak forms," and other unstressed syllables. In English, and other languages classed as stress-timed, the practice of placing stressed syllables on regular rhythmic beats typically necessitates a rapid production of the unstressed syllables. Compare, for example, the sentences:

1. Last October Jane got sick.
2. Last October Jane had an accident.

In the first sentence, the same number of unstressed syllables follows each stressed syllable, making it easy to produce a rhythmic pattern. In the second sentence, the final interval, Jane had an ac-, contains two unstressed syllables, whereas previous intervals contained only one (Last Oc-; -tober). This means that in order to produce a regular rhythm across the stressed syllables, a speaker would have to pronounce twice the number of unstressed syllables in the same time interval which previously held only one. Furthermore, the fewer unstressed syllables occur in a given interval, the more time their speaker has for the production of the stressed syllable. It is this variability in the duration of syllables that is the defining factor of stress-timed languages. And it is this variability that provides the main reason for the extreme shortening of unstressed syllables in English. Therefore, learners of English whose first language is less stress-timed and more syllable-timed typically produce all syllables with more equal duration, and thus may give the impression that they are stressing more words than would be expected by a listener from a stress-timed language background.

With regard to the rhythmic organization of conversational turn-taking as described by Couper-Kuhlen (1991), interactions between speakers from stress-timed backgrounds with those from syllable-timed backgrounds show no consistent comparable pattern. Szczeppek Reed (2010) investigated conversations between native speakers of British English, a variety with a strong tendency toward stress-timed rhythm, and speakers of Singapore English, a variety that has been classed as syllable-timed (Low, Grabe, & Nolan, 2000; Deterding, 2001). The data show that in any given interaction, only up to half of all turn-transitions from the British English speaker to the Singapore English speaker involved rhythmic organization. In those transitions in which cross-speaker rhythm did occur, it typically did not last longer than a single (first) syllable. This shows that while speakers of a language with a tendency toward syllable-timing seem to perceive stress-timed speech as rhythmic—as evidenced by their ability to place first syllables on the next projected rhythmic beats—they subsequently continue their turns in their own time, and according to their syllable-timed speech rhythm. In doing so, they are able to create fluent transitions; and also fluently deliver next turns.

As conversational spoken language emerges through time, and conversational utterances are placed in a temporal relation to prior utterances, timing is an inherent feature of natural discourse. Rhythm, on the other hand, can be described in terms of gradual differences: A speaker's turn may be more or less rhythmic; and a given language or variety may organize speech with different degrees of stress- or syllable-timing. Both aspects, however, impact on conversational speech in two ways. On a local level, both timing and rhythm are primary resources for participants' negotiations over turn-taking and the organization of conversational sequences. From a more global perspective, both aspects are prevalent in all speech, and exploited by conversationalists for the structuring of language in the ever-changing environment of spontaneous discourse.

Rhythm in Discourse

FREDERICK ERICKSON

Introduction

Speech is uttered in real time. It is experienced as a succession of “now” moments, each “now” preceded by an immediately past moment. The rhythmic organization of that timing contributes both to our capacities as interlocutors to communicate referential meaning with one another and to organize conjoint actions together as speakers and auditors, actions such as turn exchange, and listening responses. Moreover, the rhythmic organization of uttering speech simplifies the perceptual and information-processing tasks presented to an auditor, by marking the continuous stream of verbal and nonverbal behavior with prominence points whose emphasis underscores the current “now” moment and enables the auditor to anticipate the next “now” moment to come—a moment whose location in real time is projected by the rhythmic organization of verbal and nonverbal behavior at the current “now” moment.

The Pulse Organization of Discourse

The verbal and nonverbal behavior involved in the performance of speaking is organized in terms of an underlying *pulse* or *cadence*—that is, the periodic action of a simple harmonic oscillator that produces a rhythmic cycle, in this case a wave form of a very low frequency. The time intervals between one pulse, the next pulse, and the one after that are roughly equidistant, that is, the intervals are not exactly identical—they are not perfectly isochronous—but they vary only slightly from one to the next (as in the musical performance style termed *rubato*, in which there are slight accelerations or decelerations across successive musical “beats.” On these slight irregularities, see Osborne, 2009).

In many of the examples that Erickson and others have investigated, the pulse interval is approximately one second’s duration—varying from slightly less than one second to slightly more than one second in duration. This is within the usual time frame of resting heartbeat (hence the term “pulse”) and also of resting respiration. The pulse interval is also apparent in the alternation of steps while walking, and in military marching the periodicity of the pulse is in the same time frame as that for resting heart beat—one pulse per second (a Maelzel Metronome rate of 60). The time interval between two successive pulses determines the fundamental *tempo* of interaction—a faster tempo involves a shorter pulse interval and a slower tempo involves a longer pulse interval. In actual performance the pulse interval may vary plus or minus one or two tenths of a second, from one iteration of the pulse to the next, but overall in a series of pulses, perceived as a gestalt, there will be consistency in the pulse interval.

The pulse/cadence interval is experienced by humans in their earliest engagements in social interaction. Periodicity is apparent in the verbal and nonverbal behavior of caretakers and infants during play episodes. Malloch (1999), for example, reports that in one such episode the mother spoke to her child in bursts of speech that averaged 1.53 seconds in duration, plus or minus a maximum of 0.1 second. He shows this with a spectrograph

2 RHYTHM IN DISCOURSE

print, which was reproduced in Erickson (2003, p. 14), together with a transcription from his spectrograph. In this transcription each burst of speech begins at the left margin (two successive dots equal a half second pause):

Mo: Come on . . a-
gain
Come on then
That's clever
(baby vocalizes)
Oh yes . . is

that right . .

well tell me some more then

Gratier (1999), using a different spectrographic display, reported a similar periodicity in vocalizations between mothers and infants, with a pulse tempo of roughly five in every ten seconds. Similar timing patterns have been reported over the past thirty years by the research group led by Daniel Stern. (See, for example, Beebe, Stern, & Jaffe, 1979; Jaffe, Beebe, Feldstein, Crown, & Jasnow, 2001. See also Trevarthen, 1999, and the discussion of musical perception and cognition by Temperley, 2001.) Recent papers (Gratier, 2003; Gratier & Apter-Danon, 2009) show how this periodicity is flexible, mutually produced by mother and infant.

In speech among adult interlocutors this pulse organization is also apparent, but it is manifested in more subtle ways. Some but not all of the stressed syllables occur at a relatively constant pulse interval, and a resumption of talk may also occur on that interval after a pause in speaking has taken place. The pulse interval is also marked by various nonverbal actions performed by the speaker—occurring either simultaneously with the stressed syllable or in “substitution” for a stressed syllable—on the “beat” of the interval (e.g., the point of extension in a gesture, a shift in postural position, the onset and offset of gaze between interlocutors). Other syllables and nonverbal actions are performed more and less rapidly in accommodation to the underlying pulse interval. Some of these more rapidly occurring units project ahead toward the next pulse occurrence to come, thus successions of unstressed syllables “lean forward,” as it were—they are *enclitic* in relation to the “next” pulse that is about to occur. Moreover, the listening behavior of listeners often underscores the pulse interval: for example, nods, reaches, shifts in postural position, and verbal back channels (mhm, yeah) often occur on the “beat” of the pulse interval. Thus across the real time course of interaction the pulse interval is maintained jointly in the speaking and listening behavior of interlocutors.

Within breath groups demarcated by an overall intonation contour followed by a slight pause for a next breath, the syllable closest to the pause that is most prominently marked by an increase in pitch, or volume, or both is called the *tonal nucleus*. This syllable is not only marked by pitch, volume emphasis, both pitch and volume emphasis, or *stress*, but the tonal nucleus within a breath group usually is uttered at the pulse or cadence interval. Since, as Chafe has demonstrated (1994) the breath group is the primary information unit in speech—not the sentence per se, but the breath group—the pulse organization of speech rhythm and the capacity of speech to communicate information are fundamentally connected within the conduct of talk (see also Steedman, 1996; Wennerstrom, 2001).

In addition to providing a temporal scaffold which permits expectation of which next moments will be those in which important information will be communicated in speech, the pulse organization of talk enables the prediction of the completion of one speaker's utterance and the appropriate time for the beginning of another speaker's utterance, that is,

the pulse interval that is apparent within the performance of verbal and nonverbal actions in speaking supports expectations that help to organize turn exchange among interlocutors.

A rationale for these inferences about the functions of the pulse interval in supporting the auditor's capacity to understand what is being said as it is being uttered in real time comes from information-processing psychology. Modern cognitive psychology has identified serious limits on the amount of information that humans can perceive and comprehend in real time (Newell & Simon, 1972; Simon, 1979). In the ongoing speech stream and in the stream of nonverbal actions there is far more information present than can be processed cognitively. The pulse interval simplifies the information-processing task for auditors by enabling them to focus attention on the "now" moment—which is predictable from the gestalt/scaffold of a series of periodic previous moments. If important new chunks of information appear more often than not at a periodic pulse interval, then attention itself can be focused by auditors in pulses across time.

Examples From Oral Discourse

Here is an example from an academic advising interview in a community college (this example is discussed at length in Erickson & Shultz, 1982, pp. 86–93). The counselor had just asked the student what courses the student was currently enrolled in. He then asked about the student's academic plans for the coming semester. In the transcript, syllables receiving primary stress are shown in boldface type, at the left margin, together with a time indication calibrated in 24ths of a second, which is the speed at which sound cinema film is exposed—in the final print of the film each frame of film was successively numbered, for research purposes. Thus 24 units equal one second's duration.

C: *shifts postural position and clasps hands together*

now aaaaah

4050

pause as far as

4074

next semester

4124

pause

4150

why don't we give some

thought to ah . .

4200

pause to

4224

what you'd like to take there

4250

note pad is now in place in front of C)

pause

4274

4 RHYTHM IN DISCOURSE

pause do you
4300

plan on con-
4325

tin-u-ing along this P.
4350 (*C shifts in chair and*

E. major?
4350
rests left elbow on desk, touching chin with left hand)

pause
4400

S: yeah I

guess so . . . I might as well keep it
4424

up
4450

Notice the sequence of single syllables uttered by the counselor that receive primary stress and that occur on the pulse interval: **now**, **next**, **why**, **thought**, **what**, **take**, **plan**, (con) **tin** (uing), (P.) **E**. These are sketching, as it were, an outline of new information points that are being revealed in a temporally connected series of next moments until the overall trajectory of new information is completed:

now (*a new topic is about to be stated*)
pause (*what is the new topic?*)
next semester (*that's the new topic—next semester*)
give some

thought
pause (*thought to what?*) to
what
take (*what courses you would take*)

pause
pause do you
plan (*what plan?*) on con-
tin-u-ing (*continuing what?*) along this P.
E. (*continuing in your current course of study?*)

This idea sequence was finally completed across a series of next moments marked by stressed syllables. It was a discourse unit consisting of a shift to future time as a topic, followed by a rhetorical question ("Why don't we give some thought to what you'd like to take there?") and an actual question specifically identifying the student's major course of study ("Do you plan on continuing along this P. E. major?") After the completion of the counselor's extended utterance the student began his answer with unstressed syllables just before the next pulse interval and continued with a stressed syllable, "**guess**," on that interval, followed by a stressed on the next pulse interval: "keep it **up**." Thus the completion of the counselor's turn, with points of new information marked during the turn's course by stressed syllables on the pulse interval, was followed by the initiation of the

student's rejoinder in a turn that was also organized rhythmically in terms of the subsequent pulse intervals.

Here is another example that illustrates the timing of answer in relation to question. The following transcription shows the timing of the vowel in primary stressed syllables (in seconds and tenths and hundredths of seconds) as well as the pitch of the vowel (in Hertz units) and its volume (in decibels). As in the previous example, here the stressed syllables appear at the left margin of the transcript. This information was determined through digital recording of the speech, using the PRAAT software for acoustic analysis. Time was measured at the center of the stressed vowel, together with the pitch and volume information that appeared at that point in time. In a kindergarten-first grade classroom the teacher was conducting a mathematics lesson on sets and set properties. She had placed a set of triangle-shaped blocks on the floor and another set of blocks that were all green in color. Pointing to the set of triangle blocks the teacher said, "These blocks are all the property of the same what?" The students replied, "Shape, shape, shape" with increasing volume at each iteration of the answer:

T:	these	blocks are all the
sec	6.17	
hz	331.2	
db	74.29	
	pro-	perty of the same
sec	7.04	
hz	249.1	
db	78.99	
	what	
sec	8.24	
hz	397.3	
db	76.76	
SS:	shape	shape shape
sec	9.28	9.44 9.68
hz	372.2	324.4 335.7
db	72.32	74.99 79.86

Notice that the pulse interval between the stressed syllables in the sequence is approximately one second (plus or minus 0.2 sec). Notice also that the two "echo" answer words after the initial answer "shape" succeed the first answer and one another at an interval of 0.2 seconds.

This timing pattern can also be illustrated by quasi-musical notation, in which pitches are not indicated but the speech rhythms are shown (see Figure 1).

In analyses published separately Erickson has shown how the regularity of timing between question slots and answer slots in discourse enabled more experienced first graders in this K-1 classroom to act as "turn sharks" at the beginning of the school year, stealing answer turns from less experienced kindergartners (see Erickson, 1996; Erickson, 2004, pp. 53–71). Another discourse function of the pulse interval appears to be the discourse organization of lists in speech. List item nouns can be uttered on successive pulses

Figure 1 Musical notation illustrating the timing of an answer in relation to a question

as a way of showing semantic connections between them as members of a connected series. Erickson has illustrated this elsewhere, using quasi-musical notation to show the timing of the list item nouns (Erickson, 1982, 1992, 2004, pp. 36–48).

Conclusion

This entry has attempted to show how a basic scaffolding of timing organizes certain aspects of oral discourse in spoken English. Unstressed syllables tend to project toward those that receive primary stress within a breath group. More often than not the syllable receiving primary stress is uttered at a regular interval, a pulse interval, in relation to the primary stressed syllable in the previous breath group (and this pattern applies as well to some of the stressed syllables that are not primary within the breath group, such that the preponderance of stressed syllables within the speech stream stand in regular time relationships to one another). Emphasis points in gesture and in shifts in postural positioning and gaze often accompany or take the place of a stressed syllable of speech in marking the pulse interval. The pulse interval often is found to regulate the timing of turn exchange, and it also underscores the progressive revelation of chunks of new information. Erickson has argued that this timing framework in oral discourse simplifies the cognitive task of the auditor in tracking the meaning of what is being said and an implication of this is that our auditory and visual attention during the ongoing course of social interaction may itself occur in pulse bursts. This speculation could now be tested by continuous MRI scanning of brain function during conversational exchanges. To this author's knowledge that has not yet been done. Yet recent work on the timing organization of mother–infant interaction and on the neurobiology of musical perception (including the use of MRI scanning) and the kinesics of musical performance seems to confirm the importance of the pulse interval as an organizing device, and it seems reasonable to assume that this applies also in the real time conduct of conversation face to face among adults.

Auer, Couper-Kuhlen, and Müller (1999) in a monograph titled *Language in Time: The Rhythm and Tempo of Spoken Interaction* present numerous examples and interpretation that both support and partially contradict what is said in the previous paragraph. They acknowledge the importance of a pulse interval as an organizing device in oral discourse and they show this not only for English, a language in which syllable stress is especially heavily marked, but for Italian and German as well. They find the pulse interval to be particularly important in the regulation of turn taking. They agree that these timing patterns are an aspect of the implicit cueing systems in speech that Gumperz has called *contextualization* (see Gumperz, 1992; Auer & DiLuzio, 1992). However, they are not persuaded that the pulse interval is as ubiquitous in the organization of speech as Scollon (1983) and Erickson have claimed, and they are not persuaded by the quasi-musical notation Scollon and Erickson have both used to illustrate the timing of talk's uttering. In effect, they are concerned that we have over-interpreted our evidence, identifying stronger patterns of rhythmic integration in speech than what actually exists.

One reason for presenting PRAAT software measurements of timing in this entry, as well as timing data derived from the slow motion analysis of frame numbered cinema film, is to provide further evidence for the claims about rhythmic integration that Erickson has been making (as well as to provide independent evidence for the accuracy of the musical transcribing approach that Scollon and Erickson have used). It could be that the criticism of Auer et al. (1999) is correct and that organization of speech in terms of pulse intervals is more partial than Erickson and others have claimed. Further research is needed to determine this, including comparative study of languages to include a wider sample than those of Indo-European origin. As Erickson has reviewed a range of ethnographic films showing conversation in social interaction among Canadian Inuit speakers, Kalahari

Bushmen, Yanomamo from the Amazon river basin, and speakers of American English it appears to him that a regular pulse interval is apparent in the verbal and nonverbal behavior that occurs among interlocutors, but this remains to be demonstrated by machine analysis of the acoustic and kinesic phenomena that take place, using a wide cross-cultural sample of audiovisual recordings of interactional events.

Interestingly, a precursor to contemporary claims about the musicality of speech in English, especially concerning its timing patterns in stressed syllables, comes from an 18th-century author, Joshua Steele, who in 1775 published and presented to the president and fellows of the British Royal Society a treatise titled *An Essay Towards Establishing the Melody and Measure of Speech to be Expressed and Perpetuated by Peculiar Symbols*. The “peculiar symbols” referred to are a quasi-musical notation, using regular musical measures of two beats or three beats, showing both the rhythm of the uttering of syllables and their relative pitch levels. Among many examples, Steele included on page 47 a rendering in his notation of the manner in which he had heard the actor David Garrick deliver the beginning words of the soliloquy of Shakespeare’s Hamlet. Erickson has converted that notation into the transcription approach used in this entry:

Hamlet, Act 3, Scene 1, line 55

to
be
· · or
not to be
pause
that is the
ques-tion

Further evidence from the 18th century concerning the timing of stressed syllables in English comes from the musical genre *recitative*, in which a composer deliberately imitates the timing and pitch of ordinary speech. In Handel’s oratorio *Messiah* the following passage from the Hebrew scriptures (Isa. 35: 5–6) was set in recitative:

· · Then shall the
eyes of the
blind be
op-ened
· · and the
ears of the
deaf un-
stopp-ed

This and other examples of recitative are discussed in Erickson (2003), showing how the quasi-musical notation used by Scollon and Erickson is an adaptation of the recitative genre used by composers of the Baroque and Classical periods in music history. Handel wrote *Messiah* only about 20 years before Steele published his treatise on the musicality of speech prosody, and it is certain that Steele would have been familiar with recitative as a genre. Consider the semantic expectations set up by the grammar of the Isaiah text combined with its pulse interval organization, as the musical setting by Handel indicates it should be uttered: (*Then shall the what?*) The eyes. (*Of whom?*) The blind. (*Be what?*) Opened. (*And the what?*) The ears. (*Of whom?*) Of the deaf. (*Be what?*) Unstopped.

As a final example, consider the self-educated American statesman Abraham Lincoln, steeped in the language of Shakespeare and of the authorized version of the Bible. The

opening words of his Gettysburg Address were crafted with a high dignity and sonority analogous to that of the immediately previous examples. Again in the absence of machine recording one can only speculate how those words were actually spoken by Lincoln. But here is a hunch:

Four score and seven
 years ago . . . our
 fa-thers brought forth upon this
 con-tinent a new
 na-tion . . . con
 ceived in liberty and
 ded-icated to the propo-
 si-tion that
 all men are created
 e-qual

To conclude, there is an aesthetic aspect to the pulse interval in oral discourse as well as a possible cognitive function for it—a special resonance that the pulse interval communicates. Moreover, if the discussion and evidence that has been presented here is correct, it suggests that when actors say “wait for the next beat” they mean it literally as well as figuratively.

Risager, Karen

MANUELA GUILHERME

Karen Risager is well known to researchers working in language and culture education and intercultural dialogue across Europe and beyond. She is a Danish scholar, with a global approach to the field, whose work on the relationship between language and culture within the scope of language education (second and foreign language) has inspired and contributed to structure theoretical research and teaching practice in the field all over the world.

She was born on July 15, 1947, in Frederiksberg, Denmark, where she grew up together with a younger brother. Her only son, Kasper Risager, was born in 1980. She attended high school at Rysensteen Gymnasium in Copenhagen. While in high school, she already showed an interest in world geography and languages and studied the geography of South America as well as the Dutch language and Ancient Greek.

Professor Risager holds a master's degree in general linguistics and French from the University of Copenhagen and later (2003) became Dr Phil (this equals the German degree *Habilitation*) in Cultural Encounters from Roskilde University, to which she has been attached since 1974. For many years she taught at the French department, at the Basic Studies Program for the Humanities (HIB/ICS and HAB) and at International Development Studies. More recently, she became very active in the creation and implementation of the Cultural Encounters program, a new interdisciplinary BA, MA, and PhD program at Roskilde University that started in 2000, focusing on identity constructions in a transnational, global, and postcolonial perspective. She was appointed Professor in Cultural Encounters in 2005. She then became the director and member of the board of the doctoral program on Intercultural Studies (the research group at Cultural Encounters) and the director of the research group on intercultural studies at Roskilde. In 2008, she was also appointed the director, and later became an ordinary member, of the working group on the Danish bibliometric research indicator in the fields of anthropology, ethnology, cultural encounters, and minority studies. She has also taught subjects related to intercultural competence at many in-service training courses for language teachers and other groups. Furthermore, she has been a consultant for the Ministries of Education and of Integration on several occasions, advising on the development of foreign language studies and the study of Danish as a second language. She is also cofounder of the Danish journal *Sprogforum, tidsskrift for prog- og kulturpædagogik*.

Risager's research interest is twofold, dealing both with foreign language/culture education and with Danish as a second language. However, the core of her research interest is concentrated on a single interest, that is, on the relationship between language and culture and the various ways in which that relationship may develop during the learning of a language and of the ethnic cultures to which it relates, as well as the different circumstances of mobility that may surround and incorporate this process. It is therefore not surprising that she has become highly committed to a Danish cross-university research project on the linguistic and cultural learning processes of adult immigrants/refugees in Denmark. They are working with case material including a range of people from different parts of the world, and some of the work includes studies of the multilingual research process in relation to a range of languages. Risager is also a member of the international

research center CALPIU which is led by Roskilde University and deals with “Cultural and Linguistic Practices in the International University.”

She has applied her research interests to the development of both the cultural and social dimensions of Cultural Encounters and the more linguistic dimensions, especially on issues related to transnationalism, integration, and intercultural communication in Denmark and other countries. Another thing that fascinates Risager is the different images of Denmark created by various groups—different groups of immigrants, the tourist industry, Danes abroad, Danish media, and so forth. She is also very interested in studies of linguistic diversity and inclusive and exclusive language policies (as a part of cultural and social policies), in Denmark and in other countries. In addition, Risager has developed an interest in China, and educational relations between Denmark and China, since, in the spring of 2007, she was part of a Roskilde University delegation to several Chinese universities.

Her field of research is the relationship between language and culture, with special reference to sociolinguistics, anthropological and cultural linguistics, language and culture pedagogy, internationalization, and intercultural learning/competence. Among other things, she has been studying the images of culture and society that are created and transmitted within language teaching and citizenship teaching, mainly in foreign languages as well as in Danish as a second language for immigrants and refugees. She is especially interested in education in a global perspective (global education, world studies, education of the world citizen, cosmopolitanism), and her doctoral thesis dealt with these issues as part of a more general analysis of the relationship between language and culture. Her research on the theoretical relationship between language and culture, as well as on transnational language and culture pedagogy, has also included work with language hierarchies at international universities.

Karen Risager's publications are representative of her perspective on language and culture, both on their relationship in general and in intercultural learning and dialogue (see, e.g., Risager, 1998; Byram & Risager, 1999; Risager, 2003, 2004, 2006; Andersen, Lund, & Risager, 2006; Risager, 2007; Preisler, Fabricius, Haberland, Kjærbeck, & Risager, 2008; Risager, 2009, in press). Risager rethinks the link between language and culture, calling for a third position between the idea that the national language and culture are inseparable and the idea that language can be culturally neutral. She emphasizes the dynamic nature of language and culture by using the concept of “flow” in referring to linguistic and cultural global “flows,” and she points out the complex nature of the language–culture nexus at the local level. She develops the concept of “languaculture” (or “linguaculture”) as an umbrella term for the cultural dimensions of language. Finally, she analyzes the history of the national paradigm in international culture pedagogy and also develops a theory of a “transnational paradigm” in language and culture teaching and learning. Risager outlines the components of the intercultural competence of the “world citizen” where she points out the contemporary porosity of the national borders. Risager also explains that “the transnational paradigm rests on the recognition of linguistic and cultural complexity and on transnational flows” (2007, p. 193). This also inspires her view of the “global network of Danish speakers” who make theirs a “world language” because of their “actual geographical diffusion” (2006, p. 98). Risager has dedicated her attention to the contemporary cosmopolitan composition of Danish society, its linguistic and cultural diversity, as well as to the different approaches of immigrants to Danish society and citizenship. All the above proves the breadth of Risager's perspective on language and culture and demonstrates her vision of a multilingual and intercultural world.

Robinson, Peter

ROGER GILABERT

Born in London, United Kingdom, Peter Robinson is probably best known for his empirical studies, beginning in the mid-1990s, into the roles of attention and awareness during implicit and explicit second language learning, and the effects of task complexity on L2 learners' production and acquisition. Throughout his work in these areas he has consistently addressed the influence of individual differences in cognitive abilities on successful learning under implicit or explicit conditions, or on different types of task. His long list of academic interests and his contributions to the field of applied linguistics through journal articles, conference presentations, book chapters, and edited and authored books have revolved around three main hypotheses that he has put forward. These are the cognition hypothesis, the aptitude complex/ability differentiation hypothesis, and the fundamental similarity hypothesis, which will be further described below.

Peter Robinson obtained a BA degree in modern English linguistics and literature from the University of Wales, a PGCE in English education from the University of Nottingham, an MA in applied linguistics from the University of London, and a PhD in second language acquisition (SLA) from the University of Hawai'i. He has lived and taught in the United Kingdom, the Middle East, the United States, Australia, and Japan, where he is currently professor of linguistics and SLA at Aoyama Gakuin University in Tokyo. He has also been visiting professor at a number of universities worldwide and has editorial commitments either as editor of book series or as editorial board member of many academic journals in the SLA field. He has also been conference chair and organizer of a number of conferences, a plenary speaker at many local and international conferences, and is a prolific supervisor of many SLA-based BA, MA, and PhD theses.

Drawing on research and theory in SLA, developmental psychology and psycholinguistics Peter Robinson developed the cognition hypothesis of adult second language learning (Robinson, 1995, 2001a, 2003a) and its associated triadic componential framework (Robinson, 2001a, 2002b, 2003a, 2005a, 2007a, 2007c; Robinson & Gilabert, 2007). Influenced by the work of Givón (1995), Cromer (1991), and Slobin (1993), the basic tenet of the hypothesis is that language development can be promoted by manipulating the design of language-learning tasks so as to progressively increase the cognitive and conceptual demands they impose on learners. In childhood, increasing conceptual sophistication promotes language development, and the shift from what Givón (1995) called the pragmatic to the syntactic mode of production. For example, children (under two years of age) are initially only able to conceptualize and talk about things happening in the here-and-now, but later, with conceptual development, they are able to talk about the there-and-then, and this promotes their acquisition of past tense morphology and deictic expressions. In this sense, conceptual development "pushes" linguistic development (see Cromer, 1991; Robinson & Ellis, 2008). By default, adult L2 learners too may draw on and attempt to communicate using the ontogenetically earliest acquired concepts first in the early stages of L2 acquisition, and will try to find the simplest linguistic means to express them. This explains why early second language speech appears similar to the speech of users of pidgin languages. Robinson suggests that interlanguage will be optimally pushed to grammaticize more complex linguistic forms if the conceptual, attentional, and memory demands of the tasks increase in ways that recapitulate the sequence of conceptual development in childhood. This is

DOI: 10.1002/9781405198431.wbeal1021

what he calls the “natural order” for sequencing task demands (Robinson, 2003a, 2005a; Robinson, Cadierno, & Shirai, 2009).

The four basic predictions of the cognition hypothesis are that if task cognitive complexity increases along certain dimensions: (a) more complex and accurate messages will be produced to meet more complex tasks demanding more attention and memory; (b) learners will pay more attention to task demands, and therefore be more vigilant, and learn more from the features in the input they are exposed to; (c) as a consequence they will retain such features in the input for a longer time; and (d) performing simple tasks first and then more complex tasks will contribute to more efficient scheduling of attentional demands, and so better performance on more complex tasks. The cognition hypothesis is also driven by pedagogic concerns, such as the need to establish criteria for sequencing tasks in a syllabus (Robinson, 2005a, 2007a, 2009), and so it has associated with it a triadic componential framework that lists potential features of tasks that are susceptible to manipulation. These include cognitive task variables (e.g., the amount of reasoning they impose on learners or the number of elements they have to deal with during task performance), interactive variables (e.g., whether information flows in a single direction or in both directions between participants, or whether there is a single solutions or a number of solutions to the task), and affective variables (e.g., learners’ aptitude or anxiety during performance).

The hypothesis proposes that tasks should be organized on the basis of their cognitive complexity (i.e., the attention and memory demands they impose on learners’ processing) alone and not on their linguistic demands, as traditional syllabi have suggested. Such progressive increases in the complexity of task demands will speed up the passage through stages in interlanguage development, and will cause more attention to, noticing of, and retention of input. A fundamental aspect of the hypothesis is that not all dimensions of task complexity will cause the above mentioned effects, and so it distinguishes between variables that draw learners’ attentional and memory resources to their performance and learning (i.e., resource-directing variables, such as the reasoning demands of the task) and those variables that contribute to task complexity but which disperse or deplete learners’ attention and memory resources with negative effects for learners’ performance and learning (i.e., resource-dispersing variables, such as not providing enough pre-task planning time).

Both the cognition hypothesis and its associated triadic componential framework have provided a theoretical basis for a wealth of empirical studies looking at the effect of task complexity on learners’ oral and written production and their learning. As is typical of emerging fields, most studies have tried to isolate a single variable from the componential framework, with few studies looking at several variables simultaneously, or at the effects of task complexity longitudinally. So far most studies have looked at the effects of increasing task complexity along the degree of past time reference (i.e., +/- here-and-now studies), the number of elements involved in task performance, and the amount of reasoning that task design imposes on learners, and they have done so with a variety of task types and mostly in monologic mode. Some examples of empirical studies on the effects of task complexity on production and acquisition include: (a) studies on task complexity and monologic oral production (Robinson, 1995; Rahimpour, 1997; Michel, Kuiken, & Vedder, 2007; Gilabert, 2007a, 2007b; Ishikawa, 2007), (b) dialogic oral production (Nuevo, 2006; Robinson, 2007c; Gilabert, Barón, & Llanes, 2009), (c) monologic written production (Kuiken, Mos, & Vedder, 2005; Kuiken & Vedder, 2007a, 2007b), and (d) recasts and acquisition (Revesz, 2009).

Despite mixed findings, as yet, concerning the predictions of the cognition hypothesis, the area of task complexity is one of the most prolific areas of task-based research within the SLA field. This is confirmed by the large number of journal articles, conference presentations and symposia, and research networks, as well as MA and PhD theses written on various aspects of the theory in the last two decades. Motivated by the tenets and

predictions of the cognition hypothesis, task complexity studies are providing more and more information about the effects of manipulating task design on language performance and development, with important implications for syllabus design, classroom practice, testing, and SLA theory.

Beyond his interest in task design and how task internal features may contribute to L2 performance and development, Peter Robinson has carried out extensive work within the area of individual differences. Taking the person-in-situation approach to aptitude of Richard Snow (1987, 1994) as a source of inspiration, the basic claim of the aptitude complex hypothesis is that rather than a single, monolithic aptitude for language learning there exists multiple aptitudes and that these should be matched to the tasks and conditions under which students learn the foreign or second language. Simply put, the theory holds that there are different bundles of cognitive abilities (e.g., ability to notice gaps in your own interlanguage, ability to remember previous input, ability to process the meaning of messages) which are called upon under different conditions of L2 learning and exposure. Cognitive abilities, such as noticing the gap or memory for contingent speech, are in turn made up of a number of other primary abilities such as perceptual speed and pattern recognition in the case of the former and of phonological working memory capacity for the latter. Robinson (2001b, 2002a, 2005b, 2007b, 2010) advances four aptitude complexes associated with four different modes of instruction or pedagogical intervention. These are recasting (i.e., correct reformulations of an error by a more proficient interlocutor), oral input flooding (i.e., input manipulated to be rich in target forms), written input flooding, and explicit rule explanation. Which combinations of cognitive abilities (or "aptitude complexes") are drawn upon will therefore depend on whether students are being exposed to explicit rule explanations or to less intrusive interventions such as recasts or incidental learning by means of input flooding. For example, to learn from a recast learners will have to draw on both an ability to notice the gap (i.e., by which they notice what is missing or wrong in their interlanguage) and an ability for contingent speech memory (i.e., by which they remember what was previously said by the most proficient interlocutor), while for incidental learning through input flooding they will draw on their memory for contingent speech but also on their elaborate, semantic processing abilities.

Associated with the aptitude complex hypothesis is the ability differentiation hypothesis, which proposes that the strength in cognitive abilities contributing to each aptitude complex may vary from one individual to another. This means that, for example, a specific learner may have a high aptitude for noticing the gap in his or her interlanguage but may test low in his or her semantic processing abilities. That is, as in the case just mentioned, some learners will have clearly differentiated abilities. On the other hand, some learners may display similar strengths in all abilities, being high in aptitude on all of them, or low in aptitude on all of them. These differences in aptitude profiles, Robinson argues, explain individual differences in instructed language learning success. While still in need of more empirical studies exploring such aptitude complexes, both hypotheses lay the ground for research into the best ways of matching learners' individual cognitive differences to the instructional modes they are most likely to learn well under. Such links can be of enormous importance for successful instructional grouping and practice in foreign and second language acquisition, since matching aptitudes and instructional modes (and language learning tasks) should speed up second language acquisition processes.

Finally, the last hypothesis around which the work of Peter Robinson has revolved is called the fundamental similarity hypothesis of explicit, incidental, and implicit adult second language acquisition (Robinson, 1996, 1997a, 1997b, 2001b, 2003b, 2005c, 2007d). Largely inspired, among others, by the theories on attention and awareness of Richard Schmidt, the fundamental similarity hypothesis' basic claim is that when it comes to adult L2 learning, there are no fundamental differences between explicit and implicit learning.

This is a very similar position to the one held by Baars (2002) and Shanks and St. John (1994). All adult learning is the result of both attention to and awareness of input. Noticing (i.e., attention with awareness) and rehearsal (i.e., holding it in working memory for long enough for the new material to go into long-term memory) are necessary to learning, regardless of whether learning takes place under what laboratory experimenters call implicit versus explicit conditions. With regard to classroom learning, such noticing and rehearsal in working memory will take place regardless of whether adult learners are merely exposed to oral or written texts or whether they are receiving explicit rule explanations about how a language works. The difference lies, then, not in whether instruction is implicit or explicit, but on how much each instructional approach facilitates or enhances attention to, noticing of, and subsequent processing of forms in the input.

In sum, the work of Peter Robinson has contributed to applied linguistics from a cognitive perspective in the field of SLA. In the area of task cognitive complexity it has inspired and continues to inspire intense and extensive empirical research on the effects of manipulating task design on L2 performance and acquisition. In the area of individual differences, Peter Robinson has laid out some theoretical bases for the exploration of the links between certain combinations of cognitive abilities to success in language learning under different conditions of instructional exposure. Finally, his work has suggested that the implicit/explicit divide may not matter that much for instructed adult second language acquisition: what is more important is to develop instructional conditions (and design learning tasks) which foster the noticing and processing of new forms in the input.

Role of Deliberation in Language Policy and Planning

JOSEPH LO BIANCO

In an early phase of modern language planning and policy analysis there was a major focus on the idea of language problems and how language specialists could offer governments and other agencies solutions to these language problems. Borrowing from management theory and public administration early language planning work proposed operational models for the field involving an ordered sequence of research to understand and interventions to solve language problems. In effect this constituted the field of language policy and planning as various kinds of organized pursuit of solutions to language problems, in which the critical role was allocated to an expert language scholar. As a result language policy and planning itself became identified with procedures for analyzing language problems and the specification of protocols for how these are studied and interventions to resolve them.

A key notion imported from management theory was the central importance of problem solving, and, in turn, its assumption of an established or “objective” need or problem. Constructing a new hospital in a new residential area, or a new school in a zone where there are school-age children, or laying new tram tracks to support new model trams are all examples of “problems” or needs requiring expert assistance. Much early language policy assumed that language problems were rather like these ones, that is, uncontested social facts that correspond to the clear needs of a community. Language-planning specialists were optimistic that procedures for this kind of work would be devised and the field would achieve strong standing in academic life but would be characterized by clear links to the practical world of policy and problem solving. This optimism is reflected in Fishman’s overview from 1971:

Language planning as a rational and technical process informed by actuarial data and by ongoing feedback is still a dream, but it is by no means so farfetched a dream as it seemed to be merely a decade ago. (Fishman, 1971, p. 111)

The nature of the actual language problem would be determined by elected or appointed government officials and would preexist the processes of language planning. This approach characterized the work of many pioneers of language planning studies (e.g., Rubin & Jernudd, 1971) who famously asked *Can Language Be Planned?*; concluding that although language problems can be seen as “wicked” (i.e., complex) rather than “tame” (i.e., straightforward) they remain “policy tractable.”

The idea of “tractability” is very important to this discussion. All of the examples given above, the new hospital, school, or tram tracks, are examples of problems that would attract high if not universal endorsement from the affected and even unaffected citizens. The determination of the precise nature of the problem would come from an authoritative body (e.g., government through its transport, health, or education minister) deciding what the problem would be (problem identification), in consultation with demographic experts or transportation specialists, and of course with the affected citizens. With regard to a

language problem the next phase would involve the authority concerned commissioning language planning specialists to provide expert advice to public officials.

This is the model of Western liberal democratic governance, involving measures of democratic will and expert input, in which the ultimate point is a technical solution by disinterested experts to proffer “scientific” advice. The instruments of this advice would be surveys of language use/attitudes and public officials would then implement solutions, using classic techniques of public policy such as cost–benefit assessments to weigh up alternative courses of action.

This is the approach to language planning that typified the nation-building practices of its pioneers in postcolonial contexts in Asia and Africa in the 1950s and 1960s.

However, the ideal sketched out above often failed to produce the desired outcomes and the reasons for such failure are critically important to understand why language problems are usually more “wicked” than “tame” and therefore not always readily tractable. We can see this in the point at which the policy process most often failed, that is, its earliest phase, the one most specialists assumed to preexist the actual process of language planning: the problem identification phase. Put simply language problems are rarely objective and hardly ever uncontested.

This discussion is concerned with only one kind of language planning, leaving aside many more subtle kinds of planned language change, such as how social groups or individuals in their talk or other communication practices weigh up their expressive options or engage in self-correction, ideology displays, or impression management. Instead the discussion is on deliberate and conscious language policy making, and the proposal is to include deliberation activities with all language planning, not only with regard to solutions but also in relation to the definition of the underlying problem to be tackled, such as when governments distribute resources to support particular kinds of national language use or language education measures. Even by leaving aside subjective-personal realms of language planning and focusing on public ones we can see that the technical and scientific aspirations of early language-planning scholars are rather complicated.

The work of resolving identified language problems also involves personal and subjective realms of the actors involved, their various and sometimes incompatible interests and understandings of what is involved, who benefits, what specifically and how things are to be done, and so forth. In this regard language planning is clearly a multidisciplinary activity incorporating insights and methods from applied and sociolinguistics, economics, management theory, political and policy studies, sociology, and social psychology.

Some scholars made elaborate efforts to characterize the entire field of language problems. One impressive effort in this regard is by Hans Dua (1985). In this work Dua constructed a typology of language problems to reflect the real-world realities of Indian communication issues but this is widely applicable in other parts of the world. Observing how debates about language were posed and organized and what problems were identified and by whom, Dua was important for the whole field of language planning, arguing that the “characterization and systematic account of language problems of a speech community is a prerequisite to an adequate theory of policy formulation, language planning and language treatment” (p. 3). However, as it turns out, the characterization of problems and the participants in their definition and propagation gives rise to an almost infinite number of possibilities. In Dua’s scheme *definers* of language problems can be insiders/outsiders, politicians/bureaucrats, researchers/professionals, and “the people.” This “population of definers” gives rise to a variety of perspectives arrayed against social need defined in four ways. There are “normative needs,” in whose definition professionals or experts dominate. There are “felt needs,” in which affected groups or individuals prevail in the process of defining what will be taken to be the language problem policy making will need to solve.

There are also “expressed needs” which are those felt needs converted into action, and finally there are “comparative needs” in which a contrast is established among needs in various ways to permit discussion regarding decision making. Dua produced a matrix of problems along these lines and then organized them into how such problems are handled, in a series of oppositions, such as deeply or superficially, precisely or vaguely, among others.

The practice of specifying language problems and working out recommended treatments or solutions can be seen as theory or field building, and gave way to a later phase of critique. Most scholars identify the past decade or so of language policy analysis with “critique.” This “phase of critique” is seen to expose biases, limitations of method or conceptualization, “technicism” (i.e., a desire to emphasize scientific and technical rather than human and negotiated aspects of the field), and other problems with language planning. However, while the phase of critique has been important it has neglected to propose improvements (see Lo Bianco, 2010, for critiques). Today there is more language policy making than at any time in history. Globalization, population mobility, and technology, have added to the multilingual complexity of the world and put before public authorities all over the world issues of social interaction and the management of resources, resolution of conflicts, and so forth, all of which have language and communication aspects. In this context a more purposeful effort to improve the practices of language policy making, to build on the work of the pioneers of the field rather than to endlessly deconstruct and expose its limited perspectives or partiality, is required.

What is missing from critiques of language planning and policy, however valuable some might be in exposing limitations and biases, is the critical dimension of how language problems come to be constituted as territory for the deployment of state resources, professional activity and symbolic prominence, in other words the politics of language policy and planning. Adding this focus would foreground the subjectivity of the actors, and give us a chance to assess whether the claim of partisanship is justified. The aim should be to strengthen language policy and planning rather than to have it abandoned, to assist it to become a more important scholarly and social practice, rather than one which would wither away after being subjected to critical scrutiny. Whether critiques are substantive, ideological, or methodological they would surely be addressed, as Fishman anticipated (1994), and are today mostly dated though they tend to circulate as though describing current language-planning practices. It is true that originally some language-planning specialists were uncritical toward their own practices and interests, but since the mid-2000s language planners have engaged in extended self-scrutiny and increasingly new modes of working in the language-planning sciences are emerging. In this entry a proposal is made to introduce the practice of deliberation conferences around the approaches to language problems as described by language-planning pioneers, such as Dua, to inject a participatory and democratic mode of operation and reduce the technical dimension with its air of imposing solutions onto communities of speakers. The aim essentially is to democratize the problem-definition phase of the language-planning cycle. It will always be true that language planners are not neutral technicians but a professional class of people with interests as well as skills; too many critics, aware of this weakness, were inclined to reject language planning because of this evident presence of subjectivity. But no human endeavor is absent of the interests and perspectives of the humans who engage with it; this does not preclude the possibility of disinterested practice nor does it invalidate the need for “scientific” scholarship. To argue otherwise is to be guilty of defeatism and leave policy makers and communities without the professional guidance and scholarship of generations of language planners, and to fail to use decades of language planning research and contemplation on real-world language problems.

Deliberation is a practice of organized discussion on the problems that will be taken to be the focus of the policy exercise. Analysts and critics of language policy and planning have paid too little attention to the processes of formulation of language policies and their implementation. A serious consequence of this lack of attention to the debates and arguments that precede the formulation of language policy is that little language policy analysis has addressed the process through which language policy is made. Policy-making activity is therefore reduced to a political or administrative set of procedures and regarded as less interesting to analysts than the content, effect, or cultural and ideological meanings of the policy outcomes.

Designs of language use and change are a central academic preoccupation since the so-called “language turn” in sociology, policy studies, and other disciplines (Majone, 1989; Turnbull, 2005). At the other extreme of the continuum we find more practical and “real-world” problems. Whether in education, labor market participation, citizenship practices, or health and legal procedures, questions of communication have become central to public administration. Progressively through global migration, trade and digital media exchange most societies have become both multilingual and highly mobile.

Deliberation can combine three main kinds of language planning (status, acquisition, and prestige) by inserting a formal process whereby those affected by language decisions of public authorities, the specialists, and the authority representatives engage together in *discourse re-framing*, whose aim is to produce the conditions for more “disinterested” and cooperative consideration of what is taken to be the language problem, what research is needed to understand it fully, and what solutions emerge to tackle it. In this way language planning can be tied to public discourse in how problems are framed and represented publicly and the potential of collaborative facilitation and data to advance their resolution.

Deliberation conferences emerge from theories of deliberative democracy which has become an important feature on the research agenda of several social science disciplines. There has been a surge in theory of deliberation and interest in its practice as “discursive” democracy in recent years (Uhr, 1998). Deliberation activity is contested by those who view politics as consisting only of the play of interests and power (Shapiro, 1999), and who tend to downplay or deny a role for debate and consensus, especially for debate and consensus produced by outsiders to the realm of politics, such as academics. However, this rejection of deliberation tends to view politics as an all encompassing activity, focused only on the institutional power of government. Many institutions operate with devolved responsibility and in this jurisdictional control political processes are located much closer to the real world of activity of professionals, such as teachers in schools, or immigration officials, or translators in hospitals or in legal settings. In these, and many other settings in which the delivery of services is linked to choices that must be made about language and literacy resources and planning, deliberation organized at a local level can be highly productive and supportive of multilingual and multiliterate possibilities.

Dryzek and Niemeyer (2006) have argued that the goal of deliberation should generally be a “meta-consensus” on the range and structure of beliefs, values, and preferences, as opposed to simple agreement on a course of action, the ranking of policy options, or the content of values. Although this is the focus adopted here, the long history of research on language problems gives grounds for belief that new approaches might yield convergence of ideas and possibly even agreement on courses of action as well.

One potential of deliberation processes being included in language policy making is that the large body of applied linguistic research of recent decades could potentially be tied more closely to program delivery or to new forms of social organization desired by communities. The potential benefits include overcoming weaknesses in overly professionalized language planning that marginalize affected populations by imposing on them understandings of language problems they do not share or contest. Contemporary deliberation

practices are themselves actively designed by all affected groups and offer a promise to foster engaged citizenship and improved educational and social opportunities. The field of language planning and policy would acquire information regarding understanding of complex problems and disputes on resource allocations in educational and social activities and how problem definition is constructed in the discourse processes of communities relating to professionals, each assisting the other to refine and develop a shared representation of the task at hand.

Role of Instruction in Second Language Acquisition Theories

JESSICA WILLIAMS

Although a natural relationship between theories of second language (L2) acquisition and instruction might be expected, surprisingly the connection between many theories and instruction is tenuous, or even absent. Since it is clear that the L2 often, indeed usually, proceeds in the absence of instruction, any viable theory of L2 acquisition should specify that instruction is *not* necessary. The possible role for instruction ranges from significant to helpful to no effect or, potentially, even detrimental. First, it is important to specify the target of instruction. Is it the morphosyntactic core, or does it include the L2 lexicon, phonology, and sociolinguistic rules? Second, if instruction has a role, what kind of instruction is indicated? The answer will depend, in part, on how a given theory handles the explicit–implicit knowledge interface. Teachers and researchers have long acknowledged that learners often seem to draw on knowledge they cannot articulate, and, conversely, are able to verbalize knowledge they cannot reliably use in communication. The theories below differ considerably on their acknowledgment of this interface and how they characterize it. This list of theories is by no means exhaustive; rather, it includes those that have been the most widely discussed.

Linguistic Theory—Universal Grammar (UG)

Historically, generative theory has been the most influential in linguistics, so it is no surprise that, although it is not a theory of learning, its influence extends to L2 acquisition. According to this theory, learners come to L2 acquisition with considerable knowledge of their first language (L1) and of the linguistic principles of UG. This knowledge is abstract, tacit, and normally not accessible to introspection. Acquisition is constrained by this knowledge, and new, implicit knowledge is acquired through exposure to primary linguistic input. Formal instruction on how the L2 works can increase a learner's explicit knowledge of the language, which is neither abstract nor a true reflection of UG. Crucially, in this theory there is no interface between explicit and implicit knowledge.

The lack of interface suggests that instruction that only affects explicit knowledge will be of limited use. Yet, recent research suggests that an explicit focus on functional morphemes and their features, which may constitute an acquisitional “bottleneck,” may be useful (Slabakova, 2008). Instruction that includes input with relevant triggering data may also be helpful (White, 2007). Another role for instruction within UG is that it can inform teachers about the nature of L2 learning problems (VanPatten, 2010). Finally, other aspects of language acquisition, such as some lexical or pragmatic knowledge, which lie outside of UG, may benefit from instruction.

Skill Acquisition Theory

Skill acquisition theory is a theory of learning that explains the shift from basic knowledge to mastery. Language acquisition is much like the acquisition of any other skill (e.g.,

The Encyclopedia of Applied Linguistics, Edited by Carol A. Chapelle.

DOI: 10.1002/9781405198431.wbeal1024

multiplying numbers, riding a bicycle). It goes from an initial stage of slow and effortful behavior to fluent and effortless behavior. Initial acquisition may occur through observation or analysis by the learner, but can also result from direct instruction. The knowledge that is gained in this stage is called *declarative knowledge*. At this stage, in production and comprehension, words are retrieved one by one. Gradually, through repeated exposure and use, this is converted to *procedural knowledge*, which means that language can be used in larger, preassembled chunks that are stored in long-term memory. More practice leads to faster and more fluid retrieval. This scenario requires a permeable interface between explicit and implicit knowledge. What is learned through explicit instruction and with effort can, with practice, become implicit knowledge to be drawn on automatically and with little effort.

Skill theory posits a key role for instruction. The initial stages of acquisition benefit from careful explanation of rules, followed by deliberate practice, during which declarative knowledge remains available. Skill theory does not differentiate between modules of language, such as grammar and lexicon. However, neither does it treat all objects of learning as equal. For example, some grammatical rules are considered easier in that they can be readily articulated and have few exceptions. These are the aspects of language that are most amenable to instruction. Irregular and complex rules are learned less easily. For these, optimal instruction includes rules of thumb that approximate a rule, and continued exposure to input containing the form to be learned (DeKeyser, 2007).

Emergentism

Emergentism is another broad cognitive theory of learning in which language learning is considered similar to other kinds of learning. However, L2 acquisition poses special challenges because of the previous knowledge of the L1. Language learning is considered largely inductive and computational. Language acquisition mechanisms interact with massive amounts of linguistic data to arrive at statistical computations that impute regularities in those data. Thus, what might appear to be the learning of linguistic rules is actually the extraction of regularities from large numbers of exemplars. These exemplars are not limited to grammar rules. Rather, they are *constructions*, which include conventionalized form-meaning mappings, from morphemes to multiword chunks. Learning is based on individuals' memory of all the constructions they have seen or heard (Ellis, 2006). However, not all exemplars are equal in their learnability. For example, more prototypical form-meaning mappings are more easily encoded into memory than unpredictable mappings. In addition, language is naturally redundant, and some mappings are overshadowed by more salient cues to meaning. For example, lexical cues (e.g., *yesterday*) tend to block learning of less salient morphological cues (e.g., *-ed*) to the same meaning. Finally, form-meaning mappings from the L1 may impede learning of form-meaning mappings in the L2. As a result, some aspects of the L2 may be difficult to acquire on the basis of input alone.

Learners may benefit from the instruction that draws their attention to these aspects of the L2 (Robinson, 2007). Instructional materials that highlight less salient form-meaning mappings, or explanations that point out where the L1 might impede learning, can expedite L2 acquisition. Emergentism also has implications for the sequencing of learning tasks. Increasing the cognitive complexity of communicative pedagogical tasks over time can direct learners' attentional and memory resources in ways that will encourage L2 development. More demanding tasks will place increasing pressure on the learners' developing system, forcing them to draw on more complex constructions to encode more complex concepts (Robinson & Ellis, 2007).

Input, Interaction, and Output

The input-interaction-output (IIO) approach explains L2 acquisition as a result of exposure to natural input and learners' interaction with other (native or non-native) speakers of the L2. Through this interaction, learners are able to tailor input to their learning needs, to orchestrate opportunities for output, and to modify that output to bring it into a closer approximation of the target (Gass & Mackey, 2006). Input is the driving force in language acquisition. Some forms of input, however, are better than others. According to IIO, input that is far beyond the proficiency level of the student will be less helpful than input that is closer to the learner's current stage of development. Input must be comprehensible in order to be processed and acquired.

Instructional input can be modified to increase comprehensibility. Pedagogical tasks can also be designed to encourage learners to negotiate for meaning, thereby increasing their comprehension of the input. L2 acquisition is facilitated when learners notice new forms in the input, as well as any disparities between the input and their own production. Instructional implications of IIO include: (a) enhancement of input to call learners' attention to new forms, (b) feedback on ways in which their output differs from the target, and (c) opportunities for output. Output plays a crucial although indirect role in L2 acquisition in that it allows learners to compare target input to their production and to modify it accordingly.

Sociocultural Theory

According to sociocultural theory (SCT), human mental functioning is mediated by social and cultural activities and cognition cannot be understood outside of social interaction. Indeed, mental activity arises out of the interaction of humans with one another and with the objects in their environment. Thus, although many theories separate cognitive from social activity, SCT views these as parts of a unified whole. L2 acquisition, like all learning, is a socially mediated process, in which learners move from a stage in which they are regulated by objects in their environment, to a stage in which other, relative experts, must assist them in carrying out tasks, to a final stage in which they can regulate their own performance. No distinction is made between implicit and explicit forms of knowledge (Lantolf, 2000).

There is a significant role for explicit explanation in SCT. Concept-based instruction, which is rooted in SCT, is designed to raise learners' awareness of formal properties of language and gradually increase their control over it. Crucially, explanations must include complete conceptual meanings, not simply rules of thumb. Second, instruction should lead first to awareness, but then to control and internalization of conceptual knowledge. Finally, it must connect grammatical concepts with social interaction (Negueruela & Lantolf, 2006).

Role of Language and Place in Language Policy

JOHN E. JOSEPH

In no proper sense can languages be said to belong to places. They belong unquestionably to individuals, and in a more complex way to a whole people. The complexity lies in the fact that “a people” is largely defined by its language, and vice versa, in a way that is at best dialectical, and at worst circular. Even the names used to designate peoples, places, and languages are usually variants of the same word—Finns in Finland speak Finnish—except in the case of post-imperial situations such as have left English, French, Spanish, and Portuguese as the languages of many nations, and the religious spread that has put Arabic in the same condition.

It is true that groups of people who occupy contiguous territory and see themselves as having common interests tend to develop, over long stretches of time, ways of speaking that are distinctive to them, marking them out from groups who either are not geographically adjacent to them or else are perceived as having different, probably rival interests. In other words, language does tend to mark out the social features on which national belonging will come to be based—but it is only a tendency, because it also happens very frequently that the same way of speaking is shared by people with very different interests (religious ones, for instance), and that markedly different ways of speaking exist among a group of people who nonetheless see themselves as part of the same nation.

Individuals do tend to feel that *they* belong to both a people and a place, and they can have strong views about who else does or not belong to the place they consider theirs. Language plays a cardinal role in these matters, because of how it is indexed for identities of many kinds—national, local, ethnic, religious, and many others besides. This indexicality is extremely complex, operating at many levels. It is learned by mother-tongue speakers native to the place through a long apprenticeship that starts in the cradle. It can be learned by others starting later in life, but *only with intense effort*. The degree to which an “outsider” masters that complexity readily becomes a primary index of whether, and to what extent, he or she “belongs” to the place in the eyes of others who claim it as their own.

In the 1990s the view became widespread in political science and applied linguistics that peoples possess “language rights” comparable to other types of human rights, and this has been the guiding principle of language policy for the last two decades. But language rights are connected to place in a way that few other rights are. It is assumed that they apply to a people in their ancestral homeland having the right to use their traditional (or “heritage”) language, as opposed to the national language which is generally used for official purposes and as the language of education. These rights are taken to have a greater legitimacy than whatever rights are possessed by relative newcomers to the place, even when the newcomer immigrants are more numerous than the heritage language speakers—indeed, even when the immigrant language is alive and vibrant, and the heritage language no longer has any monolingual speakers and is rarely used by persons under the age of fifty.

In this sense, language and place are a limit on democracy. The same rights are not shared by everyone in the polity; the voice of those with a claim to belong legitimately to the place counts for more than those who have come more recently. Why then has language

policy in democratic regimes evolved in this direction? Generally in order to resolve past wrongs. The heritage languages in question inevitably have a history of having been repressed by a central government which, in the past, based language policy on the principle that the way to ensure equal political rights for everyone in the country was to make sure that they had equal access to the national language, in education, broadcasting and, insofar as possible, everyday life. It was never the case that such actions from the central government had no support in the populations whose language they were trying to eradicate: the more “progressive” elements in those populations agreed unsentimentally that all would be better off speaking the national language, especially if it was a “world” language, than that of their own locality.

Every place is multilingual, indeed “heteroglossic” in Bakhtin’s (1981, written in 1934–5) sense that all linguistic activity consists of a multiplicity of different ways of speaking that are constantly intermingling with each other. For Bakhtin,

A unitary language is not something given but is always in essence posited—and at every moment of its linguistic life it is opposed to the realities of heteroglossia. But at the same time it makes its real presence felt as a force for overcoming this heteroglossia, imposing specific limits to it. (Bakhtin, 1981, p. 270)

The impetus for overcoming heteroglossia is strong enough for its omnipresence to be regularly swept under the rug, and for the myth of monolingualism to be maintained in spite of all the evidence of multilingualism. Or indeed the reverse: certain places proclaim themselves to be multilingual when, in fact, they contain a relatively small proportion of multilingual individuals; the “multilingualism” of these places consists in the presence within them of segregated communities of monolinguals.

In the worst instances, strong ties of language and place can be invoked to justify policies of “ethnic cleansing” or genocide. Hitler attempted to justify his initial invasions of neighboring countries on the grounds that these German-speaking peoples were inherently part of the German nation; and, as Hutton (1999) has shown, his policies of oppression and ultimately extermination of the Jews were underpinned by the argument that, although their language, Yiddish, was a form of German, they had the perverse racial peculiarity of not being able to have a “mother tongue.” They therefore did not belong to the German body politic but were a parasite within it.

Such beliefs emerged as unforeseen implications of German Romantic views on the origins of languages and how they are supposedly bound up with national mentalities. Despite apparently being discredited on account of the uses made of them by “scientific racism,” such views continue to have a powerful hold on the imagination. The “Sapir-Whorf hypothesis,” which partly reflects this heritage, continues to be one of the most widely known ideas of modern linguistics and is all that some students in adjacent fields know of linguistics. Sériot (2004) makes a penetrating critique of the form of semantic analysis developed by Wierzbicka (1997), whose work is based on the idea of semantic primitives that underlie all languages. In Western Europe, says Sériot, she is read as a universalist, and one of the bases on which her work is criticized is that it seems to work deductively from *a priori* principles rather than inductively from comparing actual language data. In Eastern Europe, however, she is read with the focus on how her semantic primitives are realized in such strikingly different ways in different languages, so much so that Polish and English ways of thinking appear to be strongly contrasted because of how the lexicon and grammar realize the semantic primitives differently. She is received, in other words, as a neo-Humboldtian linguistic determinist, and Sériot shows close parallels between Wierzbicka’s conclusions and those of the Nazi linguist Leo Weisgerber. There is of course no implication whatever that Wierzbicka is a Nazi sympathizer. It is not even clear whether

the “Eastern” readings of her work that give rise to the parallel are ones she intended, and in a vivid reply to Sériot (Wierzbicka, 2008) she has made clear that she does not endorse them. But what Sériot shows is that this way of thinking about language and mind has a deep and enduring appeal.

Some of Wierzbicka’s Eastern readers (e.g., Waşık & Waşık, 2004) use her views to support a critique of “linguistic imperialism” (see Phillipson, 1992), a belief that other, “bigger” languages are destroying their own language from the inside out. In other words, multilingualism is a *temporary phase* in language shift, the take-over of one language by another. This brings us to language policy, a field with a history of shifting but always ambivalent views about multilingualism (see Spolsky, 2004; Wright, 2004). When it emerged in the 1950s and 1960s as “language planning,” it was mainly about limiting what was seen as the negative effects of multilingualism for the development of emerging postcolonial nations.

Multilingualism was regarded as “impossible” in the sense that we speak of an “impossible” situation, that is, one that exists but that has to be put to an end, or at least tempered, to achieve a goal regarded as essential. But after 1989 the perception gained ground that actually societal multilingualism was becoming impossible in the more usual sense, because English and other world languages were wiping out smaller languages across the globe at an unprecedented rate. Of course the use of “unprecedented” here is pure hype: no one knows anything about historical rates in this area, and it is certainly true that languages have arisen and disappeared everywhere and at all times. In the 1870s there was also a widespread perception that English was taking over the world, fueled by unprecedented developments in communications technology—the telegraph—transportation and mass immigration (see Joseph, 2004). And in the 1920s and 1930s the Soviet linguist N. J. Marr developed his theory of stadialism, which held that the languages of the world were steadily reducing in number and merging structurally. Marr is generally regarded as not entirely sane, and yet by seeing multilingualism as ultimately unsustainable, he would fit in perfectly well today at a conference on language policy, though he would not agree with the others present that anything they might do would put off the inevitable arrival of monolingualism.

This is all very strange to applied linguists who are involved with the teaching of English, since we see ever increasing evidence of diversity, new Englishes, which is to say new languages arising across the world where English is spoken, less rather than more mutually intelligible with each passing year. From our perspective, multilingualism looks very robust indeed, and Canagarajah (1999) and other proponents of “resistance” and “appropriation” are right to insist that the critics of “linguistic imperialism,” while they are not completely deluded by any means, fail to appreciate the agency with which peoples across the globe are generating new languages using recycled materials. For Canagarajah, the principal strategy for combatting the global hegemony of English is to (re)incorporate mother tongues into the teaching of the target language. This not only validates the mother tongue in the students’ eyes, but also helps challenge English by encouraging the encroachment of mother-tongue structures into “the very grammatical and discourse system of English”—in other words, resistance. Resistance increases the chances that students will feel that the (inter)language *belongs to them*—that is what is meant by appropriation.

Perhaps the most radical attempt at undoing any connection of language and place in language policy has been the critique launched and maintained by Davies (1991, 2003) against the concept of “native speaker” in applied linguistics. For Davies, the native speaker is a myth with dangerous and destructive consequences for language teaching and testing. It is mythical because, in reality, there is no clear boundary between native and non-native speaker. Some people are able to learn a language, even starting in adulthood, to a level that makes them all but indistinguishable from a native speaker (though it appears that fine differences in grammaticality judgments always remain). The myth is destructive,

Davies believes, because, in supporting the idea that language learners can never attain their goal, despite their best motivation, talents, and efforts, by virtue of where they were born and raised and other factors beyond their control, it is an unjustifiable form of social exclusion that applied linguistics should attempt to fight rather than to reinforce.

Role of Linguistic Human Rights in Language Policy and Planning

TOVE SKUTNABB-KANGAS

Introduction: Linguistic Human Rights as Part of Language Policy

Linguistic human rights (LHR) can be defined as “only those language rights . . . which are so basic for a dignified life that everybody has them because of being human; therefore, in principle no state (or individual) is allowed to violate them” (e.g., Skutnabb-Kangas, 2008, p. 109; see Skutnabb-Kangas, in press-a, for a discussion of definitions). For basic presentations of LHR, including Web sites for all human rights (HR) instruments below, see Skutnabb-Kangas, 2000, in press-a, in press-b).

LHR can be *negative* (or *non-discrimination*) or *positive* (or *affirmative*) rights. Negative rights forbid discrimination on the basis of various characteristics, for example language. Positive rights, according to Max van der Stoep (1999), encompassing affirmative obligations beyond nondiscrimination, include a number of rights pertinent to minorities simply by virtue of their minority status, such as the right to use their language. They are necessary because a pure nondiscrimination norm could have the effect of forcing indigenous/tribal peoples and minorities (hereafter ITMs) to assimilate to a majority language, effectively denying them their rights to identity.

LHR can be discussed from an *instrumental* point of view, seeing languages purely as means of communication, or as markers of identity, with an *expressive* interest. LHR can be *individual*, as in Article 30 in the United Nations *Convention on the Rights of the Child* or in the UN *Declaration on the Rights of Persons Belonging to National or Ethnic, Religious and Linguistic Minorities*. They can also be *collective*, as in the UN *Declaration on the Rights of Indigenous Peoples* (UNDRIP) and the Council of Europe’s *Framework Convention for the Protection of National Minorities* (even if both are constantly jumping between individual and collective levels) (all emphases added). LHR can be *personal* (a person has them, regardless of where in a country she or he lives) or *territorial* (as in Switzerland: people have language-related rights only in the cantons where a certain language—German, French, Italian, or Romansch—has been designated as official, but not in other cantons), or a combination of these (as in Finland). Finally, languages themselves (rather than speakers/signers) can also be granted rights (as in the *European Charter for Regional or Minority Languages*). All of these rights are necessary, and there is no conflict between the various types of right.

Granting (or not granting) LHR to everybody should be seen as a part of a country’s or region’s language policy and planning (LPP). Language policy (LP) has been defined as

[a] systematic, rational, theory-based effort at the societal level to modify the linguistic environment with a view to increasing aggregate welfare. It is typically conducted by official bodies or their surrogates and aimed at part or all of the population living under their jurisdiction. (Grin, 2000, p. 7)

2 ROLE OF LINGUISTIC HUMAN RIGHTS IN LPP

However, this definition excludes, more or less, LPP initiated, applied, and fought for or resisted by those who are “targets” of some language policies, such as ITMs; the following definition expands the scope:

Sociocultural process that includes official acts and documents as well as everyday language practices that express normative claims about legitimate and illegitimate language forms and uses, and have implications for status, rights, roles, functions, and access to languages and varieties within a given polity, organization, or institution; the scholarly study of how decisions about language are formulated and implemented, often considered a subset of language planning. (Skutnabb-Kangas & McCarty, 2008, p. 9; see also McCarty & Wyman, 2009, p. 280 quoted below)

Various monitoring and complaint mechanisms in international law can partially make them agents in LPP, but only *after* the policy has been set by “official bodies.”

Recourse to LHR can be seen as representing one strategy in LPP. It can use international law as an instrument to “modify the linguistic environment.” This strategy can be used by “official bodies” (e.g., government or local authority representatives), when they are engaged in national and international *normative standard setting* (e.g., negotiating, signing, and ratifying HR instruments, or deciding on official or teaching languages—*status and acquisition planning*—but also when standardizing the corpus of languages, through grammars, dictionaries, and curricula, *corpus planning*). They can also *implement* various linguistic human rights, for instance in education, even those which are not demanded by international law.

The human rights system can also be used in attempting to influence governments that are otherwise committed to the gospel of neoliberalism or are in other ways *not* aiming to “increase aggregate welfare” of the population, such as Turkey vis-à-vis the Kurds (Skutnabb-Kangas & Fernandes, 2008). ITMs themselves can and do also refer to LHR when demanding rights. Often knowledge about LHR or lack of them, or about endangerment of ITM languages, plays a catalytic role in creating a movement for demanding LHR and other HR. LPP also happens through innumerable daily actions when people choose which language to speak to whom and when (*discourse planning*, Lo Bianco, e.g., 2010). *Technological planning* (Rannut, 2009), especially for demographically small languages, is also often initially bottom-up work. It is important to see LPP as both top-down and bottom-up, as a “multilayered sociocultural (and therefore political) process—complex modes of human interaction, negotiation, and production, mediated by relations of power . . . to illuminate crosscutting themes of cultural conflict and negotiation, identity, ideology, and linguistic human rights” (McCarty & Wyman, 2009, p. 280).

Supplying or Denying Linguistic Human Rights: Good or Bad Language Policy Circles

When the government provides or guarantees ITM language services, it is responsible for the “*supply increasing*” side of LP (see Grin, 2000, p. 53). A state can also *decrease supply*, for instance by stopping the training of minority mother-tongue teachers (as in Sweden in 2001), something that has been criticized by the Advisory Committee monitoring the ratifying countries’ governments’ behavior in relation to Council of Europe’s *Framework Convention for the Protection of National Minorities* (see above). Likewise, states that deny access to free and compulsory basic education (which is a human right) are restricting supply. Almost 100 countries have introduced school fees for basic primary education, often prompted by the World Bank’s and the International Monetary Fund’s structural

adjustment demands. This fact has been strongly criticized by the former United Nations' Special Rapporteur on the Right to Education, Katarina Tomaševski (2001).

LHR can also be used as a "*demand-increasing*" mobilizing strategy, often by the ITMs themselves, with goals at several levels, locally, nationally, and internationally. Competence in a language increases when it is being used. Becoming/being competent in a language (here, in an ITM language) makes people realize that the language could be used in new areas/domains (for instance in formal education, rather than only at home, in informal education). This awareness may lead to demands for being allowed to use it in those new domains. Demand increases with use and if demands are being met by the government (or some other body, including the minority itself), which increases the supply side, this enables still more use.

If the supply side again increases as a result of this demand (so that, for instance, mother-tongue-medium—MTM—education is offered and minority-language teachers are being trained), this mutual positive influence may eventually lead to a "normalization" of a minority language's position: a situation where it *can* be used (government responsibility) and *is being* used (joint responsibility for minority and government) for many or most official purposes, in addition to private use. Its knowledge becomes a valued resource—linguistic capital which is then convertible to other forms of capital. This happened with the Catalan and Basque languages after Franco's death in Spain—the languages have been "normalized"—and is happening now in the Baltic states.

This "good LPP circle," with mutual positive influence between supply and demand, and with the goal of granting ITMs equal access to participation in society also linguistically, can harness (linguistic) human rights for democracy.

But many states are today in a "bad LPP circle": they are afraid of linguistic and other HR demands, especially demands about autonomy (minorities) and self-determination (indigenous peoples). Therefore they restrict supply (e.g., MTM education) in order to contain the demands. One example is the actions of those states in the USA that have restricted bilingual education or adopted pro-English cum anti-minority-languages legislation—or both—(see Menken, 2008, for the de facto negative LPP consequences of the No Child Left Behind policy). States refuse to grant positive LHR in education. Often they do not even want to respect negative nondiscrimination rights. Through this denial of LHR they are, instead of solving problems, breeding conflict, inviting trouble, undermining democracy, and often committing crimes against humanity. Offering education only through the medium of a language that minority students do not have full access to restricts supply; this may in time increase demand. Reasonable but unmet demands increase poverty (Amartya Sen, economics Nobel laureate; see Mohanty, 2000) and invite conflict.

Which Demands Are Justified? Is Speaking a Minority Language a Handicap to Get Rid Of?

The lively discussions about justice in political philosophy and political sciences in general, applied to minority rights (presented, for example, in Kymlicka & Patten, 2003), exemplify supply and demand well. Drawing especially on HR philosophers, researchers debate what kind of language rights can be justified on what bases: that is, which demands justify what kinds of supply. Should all inequalities that are due to characteristics not chosen by the individual be "compensated for" or "rectified" by the state? Being born to parents who speak a language that is not the dominant language in the society where the person lives, and suffering injustice if this language has low status, could be seen as a disadvantage for which an individual could justifiably demand "compensation"—that is, the state should offer more supplies, and, if so, for how long?

Most liberal political scientists do not think that states should support the maintenance of the existence of minority groups beyond present generations (see, e.g., articles by the editors in Kymlicka & Patten, 2003). They see speaking a minority language as some kind of a handicap (as in deficiency theories) to be compensated for. With this view, obviously this “handicap” should not be carried on to the following generations. If parents choose to do it, it is their responsibility. This liberal view concentrates on individual rights and therefore minority groups do not, according to many political scientists of this kind, have justifiable demands to continue their existence as minority *groups*. They are given the choice either to assimilate, or to continue *without* a justified claim for support for collective rights. The more communitarian-oriented political scientists are conspicuously absent from or silent (silenced?) in many of the most prominent debates.

There is, in theory, somewhat more “toleration” toward the demands of indigenous and tribal peoples to continue to exist as peoples, and, accordingly, toward their LHR. The UNDRIP (see above) includes some LHR that support this maintenance of ITMs’ continued existence (especially Articles 13 and 14). The four countries that originally voted against it, Australia, Canada, New Zealand, and the USA, are at the same time among the top countries in having made indigenous and tribal languages “disappear” during the last 200 years through their genocidal LPP policies—all have since conditionally accepted it.

When Can an LHR Approach “Deliver”?

From a more critical perspective, David Harvey questions whether a human rights approach can represent an effective alternative to neoliberal marketization and commodification. Undoubtedly, the neoliberal insistence upon the individual as the foundational element in political-economic life opens the door to individual rights activism. But by focusing on those rights rather than on the creation of substantive and open democratic governance structures, we may simultaneously cultivate methods that cannot escape the neoliberal frame. Neoliberal concern for the individual trumps any concern for equality, democracy, and social solidarities (Harvey, 2005, p. 176). Naomi Klein (2008) likewise shows how a human rights approach that concentrates on documenting human rights abuses, and separating these from the neoliberal economic system that *requires* them in order to come to power and to be maintained against the interests of the majority of populations, has lost its intellectual honesty and integrity. A rhetoric of military intervention so as to hinder human rights abuses has been misused by the USA and its allies when invading Afghanistan and Iraq, the underlying universalist human rights principle here being made subservient to military-corporate globalization (see Phillipson, 2009). When human rights abuses such as historical and present linguistic genocide in education are documented and discussed (see Skutnabb-Kangas, 2000; Skutnabb-Kangas & Dunbar, 2010), LHR and LPP that denies them must be analyzed within the ecolinguistic macro-level context of the economic and political systems. The linguistic capital dispossession that the denial of LHR in education amounts to also dispossesses the world of much of the knowledge on how to maintain biodiversity, vital for the existence of humans on the planet. Much of this precious nuanced knowledge is encoded in the small languages of ITMs and other local peoples. In subtractive education it does not transfer to the languages that replace the small languages. LHR are a necessary but not sufficient part of critical subaltern-as-agent-driven LPP, and they can “deliver” when treated as such.

Roles for Corrective Feedback in Second Language Instruction

ROY LYSTER

The multifaceted roles of corrective feedback in second language instruction continue to attract the attention of both researchers and practitioners interested in how it can most effectively be integrated into classroom interaction in ways that benefit second language development. In contrast to theoretical arguments that a learner's underlying interlanguage system is affected only by positive evidence and not by negative evidence, other theoretical perspectives that run the gamut from cognitively to socially oriented suggest that corrective feedback is not only beneficial but may also be necessary for moving learners forward in their second language development. For example, a cognitive-interactionist perspective of second language acquisition attributes a role not only to positive evidence but also to negative evidence in the form of feedback that triggers noticing of nontarget output; skill acquisition theory attributes a pivotal role to feedback in tandem with practice that leads learners from effortful to more automatic use of the second language; and sociocultural theory views feedback as other-regulation that provides learners with dialogically negotiated assistance as they move toward more self-regulated use of the second language.

The overall effects of corrective feedback on learners' interlanguage development have been confirmed by recent meta-analyses synthesizing findings from a range of primary research (e.g., Lyster & Saito, 2010). The topic of corrective feedback in second language instruction, therefore, is approached in this entry on the premise that providing feedback is more effective than withholding feedback. Although only oral feedback will be addressed, feedback on writing is of equal importance in classroom instruction and evokes some of the same practical and theoretical issues that will be addressed here in terms of types, functions, and effects of corrective feedback.

Types of Corrective Feedback

Among various ways of classifying corrective feedback, one well-known taxonomy is Lyster and Ranta's (1997) identification of six types of corrective feedback, which was based on a detailed analysis of teacher–student interaction in French immersion classrooms. Ranta and Lyster (2007) later suggested that each of the six feedback types could be classified as either a reformulation or a prompt:

Reformulation includes recasts and explicit correction because both these moves supply learners with target reformulations of their non-target output. Prompts include a variety of signals, other than alternative reformulations, that push learners to self-repair. These include elicitation, metalinguistic clues, clarification requests, and teacher repetition. (p. 152)

A recast is “the teacher's reformulation of all or part of a student's utterance, minus the error” (Lyster & Ranta, 1997, p. 46). Explicit correction also provides the correct form but,

The Encyclopedia of Applied Linguistics, Edited by Carol A. Chapelle.

DOI: 10.1002/9781405198431.wbeal1028

unlike recasts, “clearly indicates that what the student had said was incorrect” (p. 46). In contrast, prompts—which Lyster and Ranta (1997) referred to as *negotiation of form* and others refer to as *elicitations*—withhold correct forms and instead provide clues to prompt students to retrieve these forms from their current knowledge. The distinction between providing or withholding correct forms has proven to be a useful one in instructional settings, where teachers are able to make online decisions about whether to provide or to withhold correct forms in response to students’ errors.

Distinctions among different feedback types are less categorical when it comes to comparing implicit and explicit types, because so many variables interact to determine degrees of explicitness from a learner’s perspective. For example, the delivery of recasts varies from implicit to explicit as a function of: (a) the nature of the interactional exchange, with recasts more noticeable in explicit language-focused exchanges than in communicative exchanges; (b) the overall communicative orientation of a classroom, with recasts more easily noticed in form-focused classrooms than in meaning-focused classrooms; and (c) the orientation of individual learners, with form-oriented learners benefiting more from recasts than meaning-oriented learners. Also at the explicit end of the spectrum are recasts that are short, contain minimal changes, and include intonational stress (e.g., Loewen & Philp, 2006).

Corrective feedback considered explicit also comes in many shapes and sizes, especially in terms of *informativeness*, that is, “how much information is provided about the blame of the ungrammaticality” (Ortega, 2009, p. 75). Some explicit feedback techniques include provision of the correct form while others withhold the correct form and provide either metalinguistic information or simply a metalinguistic “clue” (i.e., not an explanation) indicating that the learner’s utterance is ill formed. Prompts also range from implicit to explicit, but are distinguishable from recasts and explicit correction in terms of what Ortega (2009) calls *demand*: “the degree of conversational urgency exerted upon interlocutors to react to the negative feedback” (p. 75).

Functions of Corrective Feedback

Recasts are by far the most frequently used feedback across a spectrum of classroom settings. Reasons abound for their ubiquity; they are considered by some to be “pedagogically expeditious” (Loewen & Philp, 2006, p. 551). Others have documented how they fulfill important discourse functions that help to move lessons ahead when target forms are beyond students’ abilities (Lyster, 1998), as well as specific scaffolding functions that promote a shift toward a more academic register, especially in content-based instructional contexts (Mohan & Beckett, 2001; Gibbons, 2003).

Recasts are also claimed to benefit second language development because they provide learners with a primary source of negative evidence. For example, Long (1996) argued that, because recasts preserve the learners’ intended meaning, they free up cognitive resources that would otherwise be used for semantic processing. With meaning held constant, recasts have the potential to enable learners to focus on form and to notice errors in their interlanguage production. Others have argued, however, that this is the case only in form-oriented classrooms where the emphasis on accuracy primes learners to notice the corrective function of recasts. Otherwise, recasts can be sources of linguistic ambiguity, owing partly to their frequent occurrence in confirmations, confirmation checks, or expansions, all intended to confirm or disconfirm the veracity of the student’s message (Lyster, 1998). Whether teachers recast ill-formed utterances or repeat well-formed utterances, their intentions appear to coincide with functions generally attributed to repetition in classroom discourse, namely, to acknowledge the content of the student’s utterance or to “rebroadcast”

the student's message in order to ensure that the whole class has heard. Carpenter, Jeon, MacGregor, and Mackey (2006) found that even adult learners, as they viewed videotaped segments of a researcher responding to a learner with a mixture of recasts and non-corrective repetition, were more likely to identify recasts as non-corrective repetition than as recasts—regardless of whether or not they actually heard the learner's preceding utterance. This may be why recasts, when considered as conversational moves comprising *negotiation for meaning* (Long, 1996), have not proven as effective in classroom settings as in laboratory settings for focusing learners' attention on form. For example, in post-secondary content-based classes of Italian as a foreign language, Musumeci (1996) reported that the teachers "supplied key lexical items and provided rich interpretations of student responses, rather than engage in the kind of negotiation which would have required learners to modify their own output" (p. 314). Similarly, in the context of content-based ESL classrooms, Pica (2002) found very little negotiation for meaning that might be expected to move second language development forward, as the majority of students' non-target utterances were not addressed in any direct way.

From a conversation analysis perspective, Seedhouse (1997) argued that teachers' preferences for implicit uses of corrective feedback mark linguistic errors as embarrassing and problematic, which in turn contradicts the pedagogical message of "it's OK to make linguistic errors" (p. 567). He argued in favor of more direct and overt corrective feedback so that "pedagogy and interaction would then work in tandem" (p. 572). From other perspectives too, researchers have argued against over-reliance on implicit feedback and instead for the use of feedback that places demands on students to self-repair. Proponents of skill acquisition theory, which contends that learning entails a gradual transition from effortful to automatic use of the target language through practice in meaningful contexts, advocate a judicious use of prompts that push second language learners to practice emergent target forms in contexts of interaction. Sociocultural theory emphasizes the importance of feedback that assists novice learners in moving away from reliance on other-repair provided by experts and toward more reliance on the self, as the expert yields control to the novice in a graduated fashion. The output hypothesis also predicts that second language learners benefit more from being pushed to retrieve target language forms than from merely hearing the forms in the input, because retrieval and subsequent production stimulate the development of connections in memory and thus move language development forward. From an overall educational perspective, increasingly handing the floor over to students in this way is an integral part of scaffolding that enables them to take more and more responsibility for their own learning.

Effects of Corrective Feedback

To examine corrective feedback in terms of its illocutionary force and propensity for pushing students to modify their output, Lyster and Ranta (1997) borrowed the term "uptake" from speech act theory to refer to the range of possible utterances made by students in response to corrective feedback. Uptake includes student utterances either with repair or still in need of repair; student utterances with repair entail either self-repair or mere repetition. A question of concern to researchers and teachers alike is whether the subsequent processing triggered by different types of corrective feedback differentially affects second language development over time—a question necessitating quasi-experimental studies of corrective feedback with pre- and posttest measures.

Lyster and Saito's (2010) meta-analysis of 15 such quasi-experimental classroom studies of oral feedback revealed three patterns: (a) Recasts, prompts, and explicit correction all yielded significant effects; (b) prompts yielded large effect sizes and proved significantly

more effective in the within-group contrasts than recasts, which yielded medium effect sizes; and (c) the relative effects of explicit correction could not be distinguished from those of recasts and prompts. They interpreted these findings to mean that classroom learners (a) can benefit from the positive evidence available in recasts as well as from the opportunities recasts provide to infer negative evidence, but (b) seem to benefit even more from the negative evidence available in prompts and from the greater demand they impose for producing modified output. That the effects of explicit correction were not distinguished from the effects of recasts and those of prompts was attributed to the types of linguistic evidence available in explicit correction and the overlaps in this regard with recasts and prompts. That is, explicit correction—similar to recasts—conveys positive evidence by providing the correct form; at the same time, explicit correction—similar to prompts—conveys negative evidence by indicating that the student's utterance was incorrect.

Some research has specifically examined the role of linguistic targets in feedback effectiveness. In keeping with observations that recasts might trigger processing mechanisms that are particularly conducive to pronunciation development, Saito and Lyster (in press) demonstrated that, in the context of form-focused instruction, Japanese learners of English receiving recasts following pronunciation errors in their use of English /r/ improved more significantly than learners receiving the same form-focused instruction but without recasts. At least two other classroom studies specifically examined the differential effects of feedback types on different grammatical targets. Ellis (2007) compared the variable effects of recasts and metalinguistic explanations on ESL learners' use of regular past tense *-ed* and comparative *-er*, features that were hypothesized to differ in terms of grammatical difficulty, with past *-ed* considered easier than the comparative *-er*. The group receiving metalinguistic explanations showed greater effects on the more difficult form than the less difficult form, whereas the recast group did not show any significant gains over the control group on any of the measures. Yang and Lyster (2010) compared the effects of recasts and prompts on Chinese EFL learners' use of regular and irregular past tense forms in English, thus targeting a grammatical feature with different realizations in form but identical semantic and functional value. They found similar effects for recasts and prompts in the case of exemplar-based learning (irregular forms) but more significant effects for prompts than for recasts in rule-based learning (regular forms).

To account for the variable effectiveness of recasts, a complementary strand of research has focused on individual differences and learner perceptions of recasts measured in terms of either immediate uptake or subsequent recall. Many studies indicate that recasts of phonological and lexical errors are more noticeable than recasts of errors in morphosyntax (e.g., Carpenter et al., 2006), and a laboratory study by Trofimovich, Ammar, and Gatbonton (2007) showed that learners with stronger phonological memory, analytic ability, and attention control abilities were more successful than learners with weaker abilities at using the information available in recasts in order to produce a target-like form several minutes later. As to whether repetitions of recasts are of any value, some laboratory studies have found that, when learners repeat a recast, they are more likely to subsequently perceive its corrective intention during stimulated recall sessions (e.g., Egi, 2010), but other laboratory studies have shown that whether or not learners modify their output immediately following recasts is not associated with actual development (e.g., McDonough & Mackey, 2006). While more research into the role of immediate repair on learning outcomes specifically in classroom settings is needed, current research suggests that positive learning outcomes are associated with self-repair following prompts but not necessarily with learner repetition following recasts, whose variable effectiveness has instead been associated with specific input features such as length and prosody.

Future Directions

Research is increasingly suggesting that corrective feedback plays a pivotal role in the kind of scaffolding teachers need to provide to individual learners to promote continued second language growth. The time is ripe for further research into this potentially rich pedagogical tool, heeding the call by Russell and Spada (2006) for greater attention to “the constellation of moderating variables that could make a difference regarding CF [corrective feedback] effectiveness” (p. 156). This constellation includes variables intersecting at cognitive, linguistic, and socio-educational levels. In cognitive terms, individual differences are worthy of further pursuit, including learners’ age: There is some evidence that younger learners are especially sensitive to the impact of corrective feedback. Further research is also warranted into the role of linguistic targets in feedback effectiveness and especially how these effects vary in conjunction with learners’ developing knowledge of the target forms. Previous research has tended to conflate this variable, failing to distinguish clearly between relatively new and already internalized forms. Also worthy of further pursuit in terms of linguistic features is research designed to tease apart the specific attributes of recasts, prompts, and explicit correction that contribute to their variable effectiveness in classroom settings. In terms of socioeducational context, further research is warranted to explore how the differential effects of these attributes vary in relation to the overall communicative orientation of the instructional setting and the second or foreign-language learners therein. A timely contribution to future research into the multifaceted roles of corrective feedback would be more nuanced and multidimensional analyses of how variables such as feedback types, individual differences, linguistic targets, and instructional settings interact to mediate feedback effectiveness.

Romaine, Suzanne

TERTTU NEVALAINEN AND MATTI RISSANEN

Suzanne Romaine (1951–) has been Merton Professor of English Language at the University of Oxford since 1984. She was born in Massachusetts and graduated from Bryn Mawr College, Bryn Mawr, Pennsylvania in 1973 (A.B. magna cum laude, German/linguistics). She took her MLitt at the University of Edinburgh, Scotland, in phonetics/linguistics in 1975, and her PhD in linguistics at the University of Birmingham, England, in 1981. Her doctoral dissertation dealt with the methodology and status of sociohistorical linguistics. Prior to her Oxford chair she was senior research scientist in linguistic anthropology at the Max-Planck-Institut für Psycholinguistik, Nijmegen, Netherlands, and lecturer in linguistics at the University of Birmingham.

Romaine has held a variety of scholarships and visiting fellowships in many countries. Of these may be mentioned the Rotary International Foundation fellowship (University of Edinburgh) and the Canada Commonwealth Scholarship (Ontario Institute for Studies in Education, University of Toronto). In 1991/2 she was Kerstin Hesselgren Professor at the University of Uppsala. This award for outstanding women in the humanities is sponsored by the Swedish Research Council for the Humanities and Social Sciences. In 2004/5 she was the Royden B. Davis Chair in Interdisciplinary Studies at Georgetown University in Washington, DC, and in 2005/6 a resident fellow at the Center for Advanced Studies in the Behavioral Sciences in Stanford, California. In 1998 she was awarded an honorary doctorate from the University of Tromsø in Norway, and in 1999 from the University of Uppsala in Sweden. In 2010 she became a member of the Finnish Academy of Science and Letters. She has given guest lectures at universities in all parts of the world and plenary lectures at numerous international conferences.

Romaine's research interests are mainly focused on sociolinguistics, especially on problems of societal multilingualism, linguistic diversity, language revitalization, language acquisition, historical linguistics and language change, and language contact in the broadest sense. Other specializations include corpus linguistics, minority languages, pidgins and creoles, language and gender, literacy, and bilingual/immersion education. She has conducted extensive fieldwork in Europe, first on the language of working-class schoolchildren in Scotland and subsequently on patterns of bilingualism and language loss among Panjabi speakers in England as well as in the Pacific Islands region. Her research has also taken her to Papua New Guinea to study the language of rural and urban schoolchildren, and most recently to Hawaii.

Romaine's first monograph, *Socio-historical Linguistics: Its Status and Methodology*, was published in 1982. This pioneering work was, with reason, regarded as one of the primary texts in the new field of variation-based historical sociolinguistics. It combines theoretical considerations of modern synchronic sociolinguistics with a careful analysis of the development of relative clause formation in sixteenth-century Middle Scots. The case study raises fundamental questions about the status of sociolinguistic theory, and shows not only how the present can be used to explain the past but also how the past is relevant in explaining the present. Romaine suggests an integrative sociolinguistic theory at the intersection of sociolinguistics, historical linguistics, and general linguistics.

Romainé's other important contributions to the history of English include Volume 4 (1776–1997) of *The Cambridge History of the English Language* (1998); Romainé was the editor of the volume and the author of the 50-page introductory chapter. She also wrote a long chapter on the contact between English and other languages for Volume 6 of the *Cambridge History*, with reference to the history of American English from its very beginnings to the 20th century. Her other contributions to the history of English consist of both general surveys and articles focusing on the development of grammatical details, such as relative clauses and the comparison of adjectives. Sociolinguistic approaches are, not unexpectedly, important in these studies.

Her other books stand as evidence of the extensiveness of her linguistic expertise in the fields of applied linguistics and the various branches of modern sociolinguistics. Of these may be mentioned *The Language of Children and Adolescents: The Acquisition of Communicative Competence* (1984), *Pidgin and Creole Languages* (1988), *Bilingualism* (1989; 2nd, revised ed. 1995, nominated for the British Association of Applied Linguistics Book of the Year), and *Language, Education and Development: Urban and Rural Tok Pisin in Papua New Guinea* (1992).

These studies are all informed by Romainé's interest in central issues in linguistic theory: language acquisition, universals, and linguistic change—without forgetting their practical implications for language policies and questions like bilingual education. In *Pidgin and Creole Languages*, Romainé defines and describes the life cycles and dynamics of the most common products of language contact, pidgins and creoles. Pidgins are found to have a structure of their own which is independent of the languages involved in the original contact. Romainé shows how the structural stability of a pidgin varies in different phases in its life cycle. Within this context, she analyses creole formation in terms of transmission, innovation, and borrowing. In *Bilingualism*, Romainé connects the sociolinguistics and psycholinguistics of bilingualism, and studies various aspects of bilingual behavior, such as code switching and language mixing. She focuses on the bilingual child and bilingualism in education, and examines common attitudes toward bilingualism and children's social and cognitive development and achievement at school. Her analysis draws on her extensive fieldwork on Panjabi/English bilinguals in Britain, and Tok Pisin/English bilingual children in Papua New Guinea. Variation and change in the English-based pidgin Tok Pisin constitutes the focus of a monograph of its own, *Language, Education and Development: Urban and Rural Tok Pisin in Papua New Guinea*.

Professor Romainé's other major monographs include *Language in Society: An Introduction to Sociolinguistics* (1994), *Communicating Gender* (1999), and *Vanishing Voices: The Extinction of the World's Languages* (2000), written jointly with Daniel Nettle. *Vanishing Voices* was the winner of the British Association of Applied Linguistics Book of the Year Prize in 2001.

Written in an accessible style, these three publications bear witness to the author's impressive command of her field. They also show the many ways in which this knowledge matters outside linguistics. In *Language in Society: An Introduction to Sociolinguistics*, Romainé emphasizes the interaction between language and society, covering issues such as language and gender, language in education, pidgins and creoles, and language change. Even with this wealth of knowledge, Romainé finds that sociolinguistics needs more empirical studies on non-Western societies and cultures. She adds that theoretical developments in the field would greatly benefit from closer collaboration between linguists and sociologists. In *Communicating Gender*, Romainé shows how culture and gender are communicated and understood through discourse. The textbook focuses on the cross-disciplinary nature of approaches to language and gender, and draws on diverse fields from anthropology to education, and communication to literary criticism. The award-winning *Vanishing Voices* addresses the extinction of the world's languages: half of them may die out in this century. Nettle and Romainé put this trend in the wider context of the threat to our ecosystem.

They defend the world's languages as the accumulated knowledge of humanity and propose that endangered languages can only be preserved by preserving the cultures and habitats of their speakers.

Suzanne Romaine's books have so far been translated into Catalan, Dutch, French, Italian, Japanese, Spanish, and Turkish. As well as editing Volume 4 of the *Cambridge History of the English Language*, she was the joint editor of *Creole Genesis, Attitudes and Discourse: Studies Celebrating Charlene J. Sato* (1999, with John Rickford), and of *Tok Pisin Texts: From the Beginning to the Present* (2003, with Peter Mühlhäusler and Thomas E. Dutton).

Romaine has published more than 150 articles covering her many fields of scholarly interest. Her most recent articles deal with multilingualism, language contact, minority languages, and the extinction of language. In the *Language and Linguistics Compass* (2007), Romaine's message is: "We should think about languages in the same way as we do other natural resources that need careful planning: they are vital parts of complex local ecologies that must be supported if global biodiversity is to be sustained."

Romaine was a member of the UNESCO Expert Group that produced UNESCO's position paper *Education in a Multilingual World* (UNESCO, 2003), and also wrote the background paper on Languages and Cultural Identities for UNESCO's report *Investing in Cultural Diversity and Intercultural Dialogue* (UNESCO, 2009).

Romanization of Vietnamese

JOSEPH LO BIANCO

Writing about East Asian language planning, Gottlieb and Chen (2001) point out that script reform and change are often synonymous with language policy. While all East Asian societies engage in forms of script planning, Korea and Vietnam stand out for the degree of their departure from the historic dependence on both imported and locally devised logographic (morpheme-based Chinese) writing. Korea's Hankul system is a consciously constructed script, sometimes described as "featural" (i.e., one in which graphemes correspond not to phonemes but to phoneme constituents such as voicing and other phonological properties), while Vietnam has adopted roman alphabetic writing with diacritic markers to accommodate spoken features of Vietnamese (D. H. Nguyen, 1992; X. T. Nguyen, 1995; Coulmas, 1996; Rogers, 2005).

The Vietnamese language appears an unlikely candidate for romanization, and yet it is one of the most successful examples of this process. Geographically the country is remote from Europe, the originating source of Latin-based writing, and culturally it resides within the East Asian sphere and shares its long reverence for literary education with an extensive classical Chinese heritage. Vietnam's experience of French colonization and the specific legacies of its anticolonial struggle, marked by nationalist and later socialist phases, forced the break in sociolinguistic conditions that permitted acceptance of script romanization. The nationalist phase won cultural elites away from the Chinese and the indigenous script varieties, while socialist ideology promoted population-wide adult literacy campaigns that recruited the nation's masses into romanized writing. The outcome was the unique national script of Vietnam, Chu Quoc Ngu, and its triumph over its orthographic rivals.

Vietnamese is the mother tongue of the more than 80 million people who call themselves *ngu'o'i Viet* or *ngu'oi' kinh*, the common language of the various ethnic groups in the political territory of the modern state of Vietnam, a language spoken in the border zones of neighboring countries, and the home language of more than one million expatriate Vietnamese, residing in Europe, north America, and Australia (Lo Bianco, 2001). Over the course of a long literary history Vietnam has used three writing systems: classical Chinese characters and two representations of Vietnamese. These are Chu nho or Chu Han, the "scholars'" script, or Han characters, which were introduced through ancient Chinese southward expansion into what is today north Vietnam, and dominated there for a millennium of Chinese rule and for centuries after under native dynastic monarchies. The Chu Nom, or Nom, is an indigenous variation of Chu Han called by D. H. Nguyen "the demotic characters." Nom was devised in the 13th century and functioned alongside, and often in opposition to, Chu Han for some 800 years, often in a division of the literary tasks of the society. The third main script developed among Catholic missionaries from Portugal and France, initially as an aid to their learning of spoken Vietnamese; it is sometimes called "roman script," Chu Quoc Ngu, but most commonly Quoc Ngu. The latter is now mostly referred to as "the national script" and since 1945 has predominated over the entire national territory and at all educational levels (DeFrancis, 1977; Lo Bianco, 2001).

The three scripts have historically performed distinctive functions within Vietnamese society and have often been associated with different population interests and with antagonistic political-religious and cultural traditions. Chu Han (Chinese in classical Chinese

characters) was the exclusive and official form for public administration. Nom arose initially as a form of resistance literature against Chinese cultural and political sway and experienced several efforts at adoption, only to be resisted and suppressed, usually by officials loyal to the inherited Confucian traditions of the court. The coexistence of the two scripts, Han and Nom, represents what can be called social digraphia, that is, the creation of a long-term and relatively stable order in which different kinds of literary purposes, audiences, and modes of production were associated with an exclusive script and language.

While it is the case that only in recent decades has there been mass literacy, Vietnam can be considered “one of the most literary civilizations on the face of the planet” (Woodside, 1976, p. 2) thanks to the historic admiration of education and the prominent place given to literacy in social arrangements. This tradition of respect for writing has made script politics especially important in Vietnam’s national history.

A pattern of separate written systems (a Confucian heritage rendered in Chu Han and a vernacular one rendered in Nom), along with their institutions and a growing canon of Buddhist literature and social observances conducted by Buddhist priests, all produced a gulf with the nonliterate majority and endured for more than 800 years. Nom attracted loyalty from radical nationalists, hostility from traditional bureaucrats, and pragmatic acceptance in the limited domain of indigenous literary production (DeFrancis 1977: 44). The highest literary achievement in the traditional canon, *Truyen Kieu*, is a Nom work by Nguyen Du, composed between 1802 and 1820. While using the outward form of Chinese characters, Nom script altered the basic system of representation, so that characters came to represent aspects of Vietnamese phonology rather than morphemes or words. The coexistence of Chu Han and Nom meant that each specialized in genres of literacy, so that total literary production was divided between poetry, novels, and creative writing in Vietnamese and public administration, scholarly, and classical writing in Chinese. Nom retained an advantage in that unlike Chu Han it was connected, however distantly, to the spoken language of the population; nonetheless, both scripts represented a barrier for the unschooled population. Many centuries later the politics of bridging this gap (Lo Bianco, 2001), this time in a struggle between Nom and Quoc Ngu, in the interests of seeking independence from French and later Japanese rule, was decisive in the struggle to win the support of the illiterate masses.

All attempts to have Nom replace Chinese writing at court were thwarted either by local interests, by Ming invasion, or by Manchu incursions, often resulting in the suppression or destruction of Nom literature. Under conditions of penetration by Western mercantile, missionary, and military adventurism from the 16th and 17th centuries, a new literary dynamic, a new form of writing and a new script politics were introduced. The defeat of the Tay Son dynasty by their rival Nguyen Anh, who enlisted the support of French military officers and ascended the throne as emperor-king Gia Long (1802–20), inaugurated Vietnam’s final dynasty. Gia Long however, reinstituted Chinese works as the prime curriculum for education and favored Chinese over Nom.

Quoc Ngu is attributed to the Jesuit priest Alexandre de Rhodes, working around 1627 and 1638, who developed a basic notational guide his Portuguese predecessors had pioneered. The new orthography was published by de Rhodes in his 1651 *Dictionarium Annamaticum, Lusitanum et Latinum* as a phonemic rendering of Vietnamese with extensive use of diacritics to indicate sound quality and as tone markers over vowels. With some modifications made by other missionaries, the system remains essentially unchanged today (Marr, 1981, p. 167).

When French dominion was established over the whole territory of Vietnam by the mid-19th century, use of Quoc Ngu was restricted to religious documents and private letters within the small community of converts and missionaries, while the goal of French rule was to establish standard French as the language of its Indo-Chinese empire. French

administration was progressively established from 1861, the same year that printing of Vietnamese commenced and Quoc Ngu entered education for the first time in its classical form as an aid to learning. Not until the first decades of the 20th century did Quoc Ngu move outside its restricted circles of use and interest when it came to be promoted by both colonialist and comprador sections of Vietnamese society, always rejected and scorned by the scholar class at court and many of those who opposed all aspects of the French presence in Vietnam. Central here was education, and in particular native teachers; as Kelly argues, "The teachers held out against the French for over twenty years, despite the capitulation of the Vietnamese monarchy" (1978, p. 97). Eventually, central too was journalism, a language domain in which Vietnamese supporters of the French were assisted by the ruling administration to set up newspapers using Quoc Ngu so as to penetrate more deeply among the population. DeFrancis characterizes the relations among the scripts and languages in the latter part of the 19th century as follows: "While Vietnamese written in Nom continued to be used as a vehicle of direct or indirect opposition to the French occupation, Vietnamese written in Quoc Ngu was more and more becoming the language of collaboration" (1977, p. 148); or, Quoc Ngu for Catholics, Chu Nom for Buddhists, and Chu Nho for Confucianists (DeFrancis, 1977, p. 149).

Quoc Ngu grew in the early decades of the 20th century as opposition to French power expanded and campaigners saw advantage in the greater ease of literacy in the script to spread their message, gradually splitting Quoc Ngu from its past association with foreign collaborationism. This sentiment of political modernization became paramount between 1905 and 1945. Among the contributing factors were a new Asian confidence after Japan's defeat of Russia in 1904–5. A key figure was Phan Boi Chau (1867–1940), a nationalist inspired by Japan's assertiveness, whose historical analysis blamed the imperial court's attachment to Chu Han and Chinese as hobbling Vietnam's ability to resist French incursions, in line with new nationalist thinking among radical Chinese elements. In 1907 he called for the full introduction of Quoc Ngu in the education system (DeFrancis, 1977, p. 163). Another decisive development was the anticolonial thinking of the Tonkin Free School, established in March 1907. Its patriotic curriculum adapted but adopted Western liberal ideas and supported the growth of a "modern" and free state rather than a return to tradition. Quoc Ngu fitted its design of mass literacy and democratization.

This cultural rehabilitation of Quoc Ngu was an essential kind of language planning, though never conceived this way, and though Western ideas would be appropriated they were linked to what became the *Dong-Du* (Eastward Movement), which pressed for a separate national education system learning from Japanese precedents and Chinese ideas about post-traditional, postcolonial directions. The net effect of the conduct of nationalist politics in French or Vietnamese through Quoc Ngu was a rapid decline in knowledge of Chinese characters and also in Nom, which depended on knowledge of Chinese character writing, though key works, including those by Phan Boi Chau, were written in Chinese. To counter its opposition France too was forced to use Quoc Ngu in its appeals to wider strata of the population. As collaborators, independence campaigners, and modernizers all had recourse to Quoc Ngu, its syntax became more flexible, stylistic innovations and suppleness were expanded, and so it carried more interesting and persuasive arguments, and even those who opposed them were forced to utilize the script. As a result language and script became enriched and extended, in users and in uses, through translations and argument. In national unifying moves both Saigon and Hanoi were active, and in political and cultural journalism, fiction, poetry, and theatre scripts, they contributed to producing an explosion of new writing in Quoc Ngu, shared by older and younger writers committed to developing a common means of expression, and ultimately a single, multifunctional, standard language. The formal end of the classical Mandarin system commenced in 1916 in Hanoi with the abolition of tertiary examinations. Chinese characters and Nom were

formally abolished in 1918 in Vietnam's cultural capital of Hue, and in 1924 political reforms introduced three years of Vietnamese in some schools (Kelly, 1978). Both Chinese and ultimately French were losing their base in schools. Quoc Ngu had served French plans to detach Vietnamese intellectuals from their loyalty to Chinese culture, but then backfired against French policy as use of Quoc Ngu was required to campaign against the inroads independence campaigners had made with the ordinary Vietnamese.

From 1940 Japan imposed itself on a war-weakened France, and their rivalry for Vietnamese hearts and minds opened spaces for further growth for Quoc Ngu. This shared power system continued until Japan's full occupation of Vietnam in March 1945 and its surrender to Ho Chi Minh in September 1945. French counterattacks resulted in nine more years of struggle until the decisive defeat of the French at Dien Bien Phu in 1954 and their permanent departure from Vietnam. The country was divided at the 17th parallel, and the involvement of American and other forces on the side of the South in the Vietnam War continued armed conflict until 1975 and reunification under communist control.

The anticolonial struggles were also an extended and extraordinary language politics, with contradictory language planning and policy, that ultimately led to the unification of the national standard language expressed in Chu Quoc Ngu. After the withdrawal of the French, university examinations were conducted in Vietnamese, and French went from being the medium of instruction to an occasional foreign language, soon supplanted by the "politically correct" languages of Russian in the North and English in the South. The victory of Quoc Ngu was attained through literacy campaigns in villages and towns all across the North and after 1975 all across the national territory. As a result Quoc Ngu occupied all official domains, levels of education, social groups, and the entire country other than minority areas. The literacy campaigns were nationalistic in content and highly ideological; they offered access to the key texts and propaganda of the Communist Party. The educational goals of the 1945 Declaration of Independence included compulsory education and "total literacy" in Quoc Ngu, along with "Popular Mass Education" including the "learning of the national script . . . [It was] compulsory and free for all Vietnamese" (UNESCO, 1984, pp. 2, 3).

In October 1945 the then president Ho Chi Minh made an appeal to "the entire people to combat illiteracy," enshrining script choice in revolutionary reconstruction (UNESCO, 1984, p. 3). In the slogans of the campaigns, such as "To combat illiteracy is to combat foreign invasion," script choice was associated with foreign or local loyalty, political ideology, patriotism, and national security, ironically validating the French colonial fear that the national language, which it sought to use to dislodge the attachment of the Vietnamese to Confucianism, would become a weapon in the Vietnamese campaign against the French as well. In several waves of popular education across the whole country, millions of people were inculcated into literacy and political loyalty and a mass compulsory language policy was effectively implemented.

The digraphia of past periods of Vietnamese sociolinguistics, with Chu Han and Chu Nom dividing the communication tasks of the nation, and then Chu Nom and French or Quoc Ngu, and then French versus Quoc Ngu, was permanently dissolved in the major transformation of the communication realities of anticolonial politics in Vietnam. Separate struggles and politics were required by intellectuals and by ideologues, by nationalists and by modernizers, but all ultimately converged around supporting the national standard form of romanized universal literacy in standard Vietnamese.

Russification in the Soviet Era

MART RANNUT

Russification is a form of linguistic imperialism (Phillipson, 1992), referring to both official and covert ethnic and language policies which were implemented by the Russian authorities during the tsarist empire and the Soviet Union, and continue to be implemented by the contemporary Russian Federation. The term comprises two different notions, one applied for domestic, the other for international purposes. The domestic application denotes forcible imposition of the Russian language and culture at the expense of the native language. Russia is a multiethnic country, and Moscow-encouraged immigration of Russian speakers into non-Russian areas aims at subtractive language shift from non-Russian to Russian and absorption of a Russian mindset. The international aspect refers to both legitimate Russian language and culture promotion and the associated positive attitudes toward Russian; but it also involves the imposition of unequal relations between Russia and the post-Soviet countries concerning economy and energy—raw materials, oil and gas—and security threats of various kind (in Georgia, Transdnistria, etc.). These are traded for concessions concerning national policies and for a privileged position for the Russian language and its speakers—the so-called “co-countrymen” (*so-otechestvoenniki*) policy. The theoretical basis of the issue is provided in Rannut (2009a, 2009b), with a historical overview in Rannut (1994).

The concept of Russification was formulated in 1833 in tsarist Russia by the incumbent Minister for Education, Sergei Uvarov (1786–1855), who introduced it in the form of Panslavism entailing three constituents: the Orthodox faith, (imperial) self-governance, and nationalism. Russification meant subordination to the Russian state, including its government and the Orthodox church. The languages of rebellious nations, such as Poles and Lithuanians, were abolished from schools and public places, and in the Caucasus several Islamic nations were deported together with their cultures and languages.

During the reign of Alexander III (1881–94) language became a prominent goal within government. All state bureaucracy, as well as schools and railway and other management, shifted to Russian, whereas before that, French, German, and various local languages were widely used. Recognition of non-Russian autochthonous cultures, languages, and peoples, which constituted half of the population, was no longer tolerated. Censorship increased, and publications and other undertakings with an ethnic flavor were outlawed.

The Soviet Union, the successor of tsarist Russia, contained over 100 autochthonous ethnolinguistic communities, 22 of which comprised more than a million individuals according to the 1989 census. According to the first all-Union census of 1926, there were more than 130 ethnic communities. Slightly over half of the population was Russian and seven-tenths were Slavic. Fifteen republics' languages were spoken by more than 90% of the population. The number of nationalities was not equal to the number of languages, as some groups switched languages and others, such as Jews and Karelians, claimed several languages as their mother tongues.

The Soviet Union was composed of ethnic units that were divided into three categories, consisting of the 15 republics, 20 autonomous republics, and 18 autonomous (or national) areas and districts, the last two categories being subordinate to the republics. Though dominated by autochthonous nations, all republics were considered multilingual and in

2 RUSSIFICATION IN THE SOVIET ERA

need of Russian as the common interethnic language. Different views on language and ethnic issues were not tolerated as the Soviet Union was politically a totalitarian regime with hegemonic control, with resources allocated by central powers in Moscow, and controlled by Russians. The Constitution was not regarded as a legal document and no free elections were held. The economy and judicial system were controlled by the Communist Party, the sole political party allowed. Non-judicial population control methods were widely used. Army, police, and the KGB operated in Russian under direct control from Moscow.

The main specific feature of language policies in the Soviet Union was the dominance of the political ideology that constituted the common core. Explicit Soviet language policy per se never existed as it was merely one dimension of Soviet Communist ideology. Ethnicity was regarded as a temporary phenomenon and an inherent feature of capitalism, generated by the capitalist form of production and doomed to perish with capitalism. The view that the problems originating from ethnicity, "the national question," had long been solved, and that there were not, and would never be, any ethnic or linguistic conflicts between nations or between the central government and these nations, was established as an ideological dogma and brooked no argument. This was based on the understanding that languages in and outside the socialist system developed according to different laws. Instead of struggle and shift, convergence and fusion were said to be blossoming. The term *gosudarstvennyi yazyk* 'national language' being an ideological taboo related to tsarist oppression, the Russian language was declared to be the language for interethnic communication (*yazyk mezhnatsionalnogo obshchenia*). The term *sblizhenie* 'convergence' was introduced, but assimilation as a term was denied, though this was the process taking place in reality. Thus, convergence (i.e., shift) to Russian by ethnic non-Russians and a decrease in the number of languages spoken were considered a positive sign of development in the direction of a Communist future.

Language variety and maintenance were seen not only as a nuisance, but as an indicator of ideological backwardness. The solution could not be the substitution of one language for another, as this would have been the capitalist way, but the elimination of the whole ethnic structure, achieved with the help of migration flows, deportations, mechanical mixing of people at their workplaces, and even mixed marriages. Such measures were implemented through the advance of the Russian language to non-Russian areas by language shift, together with migration, the shift to Russian of non-Russians in higher-status functional domains, and the simultaneous protection of Russian monolingualism in non-Russian areas by creating exclusively or dominantly Russian-language services there.

The motor of the process was the territorial rotation principle of people (through compulsory army service, prisons, Communist Party officials' appointments, etc.), producing an ever-expanding Russian-language environment. Correspondingly, the non-Russian native language maintenance system was demolished through the introduction of transitional or submersion models in education, causing obligatory language shift for higher-status functional areas. The process of convergence consisted of two stages: first, Russian became the language of interethnic communication in non-Russian areas, and in the next stage, Russian became the first language of the dominated ethnic group. The process was gradual and intergenerational.

Soviet language policy may be divided into five distinctive periods, roughly corresponding to the active rule of the Soviet leaders, all starting with an overture of vague and conflicting steps, due to the power struggle among the ruling elites. Thus, for a while, the former language policy was maintained under a new regime, and changed gradually according to the urgency and importance of the matter.

The first period, in the 1920s, was characterized by domestic wars, economic disaster, and other security threats. The central government was weak, but ideologically blossom-

ing: It was assumed that the revolution would spread from Russia to the rest of the world (the so-called export theory of Communism), and thus promoting Russian was unnecessary. Thanks to the weak central power, indigenous functionaries were used for spreading the new ideology, giving them a free hand in local language matters. This process was called *korenizatsia* 'indigenization' of the local ruling apparatus of the non-Russian areas. Several schools and courses were established to prepare local cadres, a literacy campaign was launched, and the Latin alphabet was promoted.

The second period began with Stalin's consolidation of power in the 1930s, when the state opposed and constrained any further attempt to develop and elaborate languages other than Russian. Ethnic cleansing started: Whole nations and ethnic groups were deported, including the Kalmyks, the Ingrians, the Circassians, the Chechens, the Ingush, the Jews, the Balkars, the Mesheti Turks, the Crimean Tartars, and the Volga Germans. After World War II an international form of Russification was introduced, as Russian was made the compulsory first foreign language in new Socialist countries and annexed states.

The third period started in the 1950s when Stalin's successor, Khrushchev, stopped the genocide and deportations of ethnic groups. However, his educational policy proved disastrous for minorities. In 1959 the union republics and autonomous republics passed laws on educational reforms which gave parents the right to send their children to a school where the language of their choice was used; parents who had decided to send their children to Russian schools were also given the right to choose whether or not they wanted their children to be taught the autochthonous language of the republic as a subject. Minority schools were put at a disadvantage, as they had to cope with the excessive load of teaching Russian. As Russian enjoyed higher status than most local languages, this resulted in an overall gradual shift to Russian as the medium of education. Many languages fell out of use as the media of instruction. All Karelian schools shifted to Russian at once, and the impact on the languages of Central Asia and of autonomous republics was fatal. Non-Russian schools were gradually replaced by Russian-medium ones. In the early 1960s, 47 languages besides Russian were used as a medium of instruction; by 1982, the number had dropped to 16. From the end of the 1960s higher education gradually shifted to Russian. As a result, in 1989 in the Soviet Union, education—at least, instruction in one's native language as a subject—was provided in 40 languages, and higher education was offered in 5 languages.

The fourth period, that of Brezhnev (1964–82), may be characterized by the non-neutrality of language. While in the West, languages of wider communication were presented as neutral linguistic tools, enabling larger and unrestricted communication, the Soviet language planners chose the opposite way, emphasizing the connection of ideology and language. The general thrust changed from the exclusive instrumental motivation of the previous period in language policy to an overt ideological motivation linked to identity politics.

In 1979 a special all-Union conference in Tashkent, titled "The Russian Language: The Language of Friendship and Cooperation Among the Nations of the USSR," recommended that subtractive teaching of Russian be started in preschool institutions from the age of five. The recommendations also concerned secondary and vocational schools and institutions of higher education. This was confirmed by a Communist Party Politburo meeting in 1983 and in several secret protocols. In ideology, *odnostoronneye nacionalno-russkoye dvuyazychie* 'one-sided national-Russian bilingualism' became one of the most popular terms in the Soviet language planning. The term had several deviations from the standard meaning:

- It concerned non-Russians only.
- It was seen as a transitional phase to Russian monolingualism.
- It was limited to Russian–non-Russian bilingualism.

4 RUSSIFICATION IN THE SOVIET ERA

- Bilingual speakers tended always to be seen as more cultural and intelligent than non-Russian speakers without the knowledge of Russian.
- Even a minimal knowledge of Russian qualified a person to be a bilingual.

Russification as a policy was stopped during the fifth period, Gorbachev's perestroika (1985–91), due to the weakness of central power. However, the policy's impact continued in the form of Russianization of third nations among non-Russian immigrants in national territories (Rannut & Rannut, 2010).

Russification proved to be an effective policy, resulting in the extinction of approximately one fifth of local languages during the existence of the USSR, according to census data (1926–89), with 50 languages currently either moribund or on the verge of it. After the collapse of the Soviet Union and starting with the economic revival in the 2000s, Russification within Russia has steadily increased through making the teaching of autochthonous languages to native speakers optional (i.e., the termination of the minority school system), liquidating some ethnic districts, such as the Komi-Permyak district and curbing the autonomy of others, and nominating nonspeakers of the local minority language concerned to govern ethnic districts.

Internationally, Russification has been in decline, due to the decrease of Russia's political and economic power in the 1990s. However, various models of the so-called Karaganov security doctrine have been promoted, especially toward the "near abroad" neighboring countries, where the aim is to control Russian speakers through media and entertainment produced in Russia and restricting integration to the symbolic nation, stressing the right to communicate solely in Russian. In some regions, such as Transdnistria, South Ossetia, and Abkhazia, in order to maintain control, quasi-independent political entities are formed by the Russian Army, controlled entirely by Russia, where education is provided mostly in Russian and the Russian language is maintained with military force. The post-Soviet Russification endeavors within the Baltic context are described in Hogan-Brun, Ozolins, Ramoniene, and Rannut (2009).

Sampling: Mixed Methods

KATHLEEN M. T. COLLINS

A sampling design comprises two components: the selection of a sampling scheme (purposive or probability) and a sample size. The scheme is implemented to select the individuals, contexts, groups, and observations that will serve as the sampling unit. This process is impacted by the researcher's perceptions about what constitutes credible data relative to the research question, and what are the viable ways of collecting data, given the study's scope and constraints upon resources, such as time and money. When conducting mixed methods research, termed mixed research in this entry, sampling design selection is more complex because the researcher must decide on selecting a sampling design for two or more phases of a study, and this decision accelerates the diversity of data collected and the demand on resources.

Overview of Sampling Designs

To determine the sample size for a probabilistic sample, the goal is to obtain a large enough sample to detect statistically significant relationships or differences and to limit sampling errors (i.e., differences between the sample statistics and the underlying population) (Johnson & Christensen, 2008). Optimally, this decision is based upon a power analysis, which is calculated to ascertain the degree of power necessary to reject the null hypothesis when it is false. For example, the minimum sample size recommendations for detecting moderate effect sizes in accordance with Cohen's (1988) criteria, with 0.80 statistical power, at the 0.05 level of significance is 21 per group (experimental design, one-tailed hypothesis), 64 participants (correlational design, one-tailed hypothesis), and 82 participants (correlational design, two-tailed hypothesis) (Onwuegbuzie, Jiao, & Bostick, 2004). Initially, the researcher devises a sampling frame comprising a listing of all the elements in the population of interest. To select a simple random sample, the researcher can consult a random numbers table, attach a number to each unit (individuals, contexts, observations), choose randomly a starting point, and begin to select numbers by advancing systematically in one direction (e.g., across to the right, or to the left, or up, or down).

Advanced random sampling techniques are an adaptation of simple random sampling (Johnson & Christensen, 2008). A stratified random sampling technique involves dividing the population into exclusive groups or strata based upon a specific variable (e.g., age, gender), and the researcher implements a process to choose systematically the sample. Cluster random sampling involves identifying a collective sampling unit (e.g., organizations) rather than a single sampling unit, and the sample selection occurs in one or more stages. Simple and advanced random sampling techniques generate variable-oriented numerical data. Subsequently, these data are analyzed using statistical analyses, and the researcher's goal is to formulate external statistical generalizations (Miles & Huberman, 1994). A generalization is defined as the degree that findings can be applied to the underlying population that served as the source for the selection of the sample.

Typically, random sampling schemes are linked to sample selections in quantitative designs; however, researchers implement both random sampling schemes and purposive sampling schemes when conducting quantitative research and qualitative research. For

2 SAMPLING: MIXED METHODS

example, the researcher could select a purposive sampling scheme, such as a criterion sample comprised of individuals who are chosen strategically because they represent one or more criteria, and the data generated could be analyzed using quantitative statistical analyses. Alternatively, a random sample also could be selected, and the responses could be analyzed using qualitative analyses.

Qualitative data collection and analyses continue until securing additional cases does not generate any fresh information that can be included into the thematic categories, thereby reaching informational redundancy and data and theoretical saturation (Glaser & Strauss, 1967; Lincoln & Guba, 1985; Guest, Bunce, & Johnson, 2006). The more homogeneous the sample relative to the variable of interest, the fewer the number of cases required to obtain saturation (purposive) and the fewer units (probabilistic) required to detect statistically significant differences or relationships (Guest et al., 2006; Johnson & Christensen, 2008).

Forms of Generalizations

The relationship between the sample design and the type of generalization desired by the researcher impacts credibility of the conclusions and meta-inferences. A meta-inference refers to the conclusions that are generated by integrating the inferences derived from the research activities occurring at multiple steps (conceptual, methodological/analytical, inferential [conclusions and explanations]) in the implementation of both approaches (Teddlie & Tashakkori, 2009).

The decision to utilize a particular sample in the quantitative and qualitative approaches or phases is guided by the decision to apply one or more of the following types of generalizations. Naturalistic generalizations are based upon the stakeholders'/research consumers' perceptions that the study's results are meaningful and applicable to other contexts (Stake, 2005). Analytic generalizations support the researcher's "analytic conclusions" (Miles & Huberman, 1994, p. 29), and this type of generalization is "applied to wider theory on the basis of how selected cases 'fit' with general constructs" (Curtis, Gesler, Smith, & Washburn, 2000, p. 1002). Case-to-case transfers reflect utilization of a multiple case sampling design to obtain a continuum of cases relative to the phenomenon under investigation. When formulating internal statistical generalizations, the researcher utilizes a subset of elite informants who are representative of the sample, and the findings are generalized only to that particular sample (Onwuegbuzie & Leech, 2007). External statistical generalizations refer to the degree that the findings from the randomly selected sample can be applied or generalized to the population, which served as the source for the representative sample selection.

Sampling Considerations in Mixed Research

Collins (2010) conducted a content analysis of published mixed sampling typologies, and produced the following five considerations implicit in the researcher's decision to select a sample design per phase of the mixed research inquiry. These considerations impact the degree to which the researcher maintains interpretive consistency between the sampling design implemented per approach and the credibility of the conclusions, meta-inferences, and generalizations (Collins, Onwuegbuzie, & Jiao, 2006, 2007).

The first consideration is the dependent relationship between the sampling design and the time orientation of the phases. A concurrent sampling design refers to the implementation of data collection activities and data analysis techniques in phase one (e.g., quantitative) that are independent of the data collection activities and data analysis techniques implemented in phase two (e.g., qualitative). It is at the data interpretation phase that the

analyses' results of both data sources (quantitative and qualitative) are interpreted. In contrast, a sequential sampling design refers to the dependent implementation of data collection activities and data analysis techniques in phases one and two. The dependent sequence indicates that the decisions made at phase one inform or shape the decisions made at phase two. In a sequential design, data analysis and interpretation of phase one data occur before implementation of activities in phase two. Sample scheme and sample size are integral components of a sequential design because both decisions can impact the decision to use certain types of data analyses. For example, in phase one, if the researcher collects qualitative data from a small criterion sample, the brevity of the qualitative data collected can limit the type of analyses (e.g., correspondence analysis, factor analysis) that could be implemented in phase two (quantitative).

A second sampling consideration is the relationship between the quantitative and qualitative samples selected for each stage of the study. These sampling relationships are identical, parallel, nested, and multilevel (Onwuegbuzie & Collins, 2007). Identical samples comprise the same sampling units (e.g., 40 health professionals) participating in both the quantitative phase and qualitative phase of the study. Parallel samples are composed of different sampling units (e.g., individuals) participating in each of the phases; however, the sampling units are selected from the same population of interest (e.g., two separate samples of health professionals). A nested sample comprises a subset of sampling units (e.g., settings) that are selected from the larger sample. For example, the larger sample consists of 40 health clinics that participate in one phase and the nested sample comprises 10 health clinic selected from phase one to participate in phase two. Multilevel samples consist of two sets of sampling units (e.g., contexts) that are selected from different populations (e.g., urgent care facilities and hospitals); however, each sample represents a different level of engagement with the variable that is the mixed inquiry's focus (e.g., disease prevention and clinical care).

Utilizing identical samples provides to the researcher the option to place equal emphasis on both data sources when drawing meta-inferences and generalizations. In contrast, the remaining types of relationships between samples could limit interpretations in terms of sample integration, unless the researcher prioritizes one set of findings (e.g., quantitative) in contrast to the other set (e.g., qualitative) when drawing meta-inferences and generalizations (Onwuegbuzie & Johnson, 2006).

The third consideration is the relationship between the combination of sampling schemes and the type generalization selected by the researcher (Onwuegbuzie & Collins, 2007). Utilizing a probabilistic random sampling scheme permits the researcher to apply an external statistical generalization, assuming that the representative sample is large enough to detect statistically significant differences or relationships. However, when using a non-random or purposive sampling scheme, the researcher is likely to apply the other types of generalizations. The types of generalizations available to researchers are summarized in the preceding section.

The fourth consideration is the relationship between the types of data collected, quantitative only, qualitative only, or a combination of both types, and the degree that these data types address the research question (Teddle & Yu, 2007). The sample design impacts the degree of diversity represented in the data sets collected in the study. A researcher can collect a combination of both types of data, such as numerical or variable data and narrative or case data. The analyst would conduct analyses that are customarily associated with each form of data collected; specifically, numerical data are analyzed using statistical techniques, and the case-based data are analyzed using qualitative techniques. A researcher also can collect one form of data in a study (quantitative data or qualitative data), and conduct a cross-over analysis (Onwuegbuzie & Combs, 2010). For example, the researcher collects qualitative data (e.g., open-ended questionnaire responses), and these responses

4 SAMPLING: MIXED METHODS

are analyzed using qualitative techniques. The emerging themes are quantitized or converted into numerical data and analyzed statistically (Tashakkori & Teddlie, 1998). Alternatively, the researcher collects quantitative data in the form of Likert-formatted responses in a questionnaire; these responses are analyzed using quantitative techniques. The quantitative results are transformed (qualitized) into narrative data or profile data that are analyzed using qualitative techniques (Tashakkori & Teddlie, 1998).

The fifth consideration involves the researcher determining the emphasis (dominant or equal) that will be placed upon each phase when formulating conclusions, meta-inferences, and generalizations (Onwuegbuzie & Collins, 2007). When implementing a dominant emphasis, the researcher places priority on one phase (e.g., qualitative) in contrast to the emphasis placed by the researcher on the other phase (e.g., quantitative). Conversely, when implementing an equal emphasis, the researcher places equal weight upon data analyzed from both approaches. The decision pertaining to the emphasis is influenced by the type of generalization desired by the researcher and meeting the requirement for transferability. Subsequently, the researcher might decide to implement a “representativeness/saturation tradeoff” by emphasizing selection of a representative sample to acquire “breadth of information” in contrast to selecting a sample to acquire saturation or “depth of information” or vice versa (Teddlie & Tashakkori, 2009, p. 184).

Sampling Challenges in Mixed Research

There are four distinct challenges impacting sampling decisions (Collins, 2010). “Representation” refers to the challenge of selecting samples that will enable the researcher to collect credible data comprising both numbers and narratives. The researcher’s goal is to collect quantitative data that have adequate power to detect statistically significant differences or relationships, and to collect an adequate amount of qualitative data to reach data saturation, and to reflect the sample’s voice. “Inference legitimation” refers to the challenge of implementing a sampling design that allows the researcher to formulate credible conclusions, meta-inferences, and generalizations (quantitative) and to maximize descriptive validity and transference (qualitative) (Maxwell, 1992; Onwuegbuzie & Johnson, 2006).

The challenge of “integration” reflects the degree to which the sample design addresses the study’s mixing goal, objective, purpose, and research question, and the degree to which there is a balance between the sample size per approach in terms of drawing conclusions, meta-inferences, and generalizations (Collins, 2010). Last, the challenge of “politics” relates to the degree to which the findings per phase are clear and balanced relative to addressing the study’s mixing goal (e.g., study’s long-term aim, study’s impact on stakeholders) (Collins, 2010).

Hypothetical Mixed Research Study

Table 1 outlines the process a researcher might implement to address each of the aforementioned challenges by outlining the interconnections between sampling decisions and the sampling challenges associated with mixed research. As a context for interpreting these decisions, assume that in this hypothetical study, the sampling design consists of a multilevel sample consisting of two sets of individuals who represent varying levels of engagement with the variable that is the mixed inquiry’s focus. In the quantitative phase, the sample comprises 85 participants who were selected using a cluster random sampling scheme, and who participated in an experimental design. The qualitative sample comprises 19 respondents who participated in a focus group. The researcher’s intent is to make external statistical generalizations and analytic generalizations.

Table 1 Application of four mixed challenges to a hypothetical study

<i>Type of mixed challenge</i>	<i>Potential impact of sample design</i>
Challenge of representation	The researcher selected a random sample for the quantitative phase consistent with the power analysis (84 participants). The researcher conducted a member check (i.e., to ask the qualitative sample [19 participants] to review the focus group transcripts prior to analysis) (Lincoln & Guba, 1985) to maximize descriptive validity (Maxwell, 1992).
Challenge of legitimation	The researcher implements a “representativeness/saturation tradeoff” (Teddlie & Tashakkori, 2009, p. 184). The researcher places more emphasis on the results generated from the quantitative phase because the sample is larger, and was randomly selected. This decision allows the researcher to make an external statistical generalization based on the quantitative results, and to utilize the qualitative results for context-specific interpretations, and analytic generalizations (Curtis et al., 2000).
Challenge of integration	Implementing a representativeness/saturation tradeoff allows the researcher to maintain interpretive consistency (Collins et al., 2006, 2007) between the sampling design implemented per approach, and the credibility of the conclusions, meta-inferences, and generalizations drawn at the study’s conclusions.
Challenge of politics	The goal of the study is to obtain information from stakeholders. Researcher implemented a multilevel sampling design (i.e., stakeholders who have a different level of involvement with the variable of interest), and collected two different forms of data (intervention data and focus group data). Both decisions elevate the diversity of data analyzed, thereby expanding the options to address potentially the challenge of politics.

Note. Please see Collins (2010) for an expanded discussion of these challenges.

Sampling: Quantitative Methods

JAMES DEAN BROWN

What Is Sampling?

Sampling is the act of choosing a smaller, more manageable subset of the objects or members of a population to include in an investigation in order to study with greater ease something about that population. In other words, sampling allows researchers to select a subset of the objects or members of a population to represent the total population. Sampling is used in language research when the objects or members (hereafter simply *objects* or *members*, but not both) of a population are so numerous that investigating all of them would be unwieldy. Such objects of study might include the total populations of all ESL learners, TOEFL examinees, essay raters, words, cohesive devices, and so on. For instance, to study the test scores of the roughly one million TOEFL examinees in a given year, a researcher might sample just 15,000. Sampling can thus increase the researcher's efficiency by minimizing the resources and effort needed to conduct the project (Brown, 2001, p. 71), while at the same time increasing the speed, scope, and accuracy of the project (as explained in Cochran, 1977, pp. 1–2).

Populations and Samples

Two words, population and sample, are key to understanding the more general concept of sampling. A *population* is the entire set of objects that are the focus of a research project. Let's say a researcher wants to study all the examinees who took the TOEFL in 1991. Few language researchers have the resources to collect and analyze a data set of a million test takers. So those researchers might take a sample of say 15,000 of the TOEFL examinees in one month of 1991 (as in Brown, 1999). This sample of 15,000 examinees who took the May 1991 TOEFL is meant to be representative of the entire population of those who took similar TOEFL tests in 1991 and beyond. If the data were appropriately sampled (i.e., the sample is actually representative of the population), the results of the study should also be approximately representative of results that would have been found if the study had been conducted using the total population.

Probability Versus Nonprobability Sampling

Sampling can be of two broad types: probability or nonprobability sampling. *Probability sampling* "has the characteristic that every element in the population has a known, nonzero probability of being included in the sample" (Levy & Lemeshow, 1999, p. 20). The advantage of probability sampling is that, one way or another, the objects are selected randomly into the sample, and thus the probability of each object being in the sample is nonzero and known. Table 1 shows that probability sampling can reference one of three things: the entire population, strata within the population, or clusters within the population. In these cases, the samples are often referred to as simple random, stratified random, or cluster random samples, respectively.

Table 1 Probability and nonprobability sampling procedures

<i>Sample reference</i>	<i>Probability sampling</i>	<i>Nonprobability sampling</i>
Population	Simple random sample	Convenience sample
Strata	Stratified random sample	Stratified sample
	Quota	Quota
	Proportional	Purposive
Clusters	Cluster random sample	Cluster sample
	Quota	Quota
	Proportional	Purposive

Nonprobability sampling techniques do not use random sampling. Hence, each object in the population does not have a known, nonzero probability of being selected for the sample. Table 1 shows that nonprobability sampling can also reference the entire population, strata within the population, or clusters within the population. In these cases, the samples are often referred to as convenience, stratified, or cluster samples, respectively.

Methods of Probability Sampling

Simple random sampling at first seems straightforward because it only requires that each object in the population have an equal chance of being selected. However, problems arise when we look at the three steps (adapted from Brown, 2001, p. 72) that are necessary to make sure each member of the population has an equal chance of being included in the sample:

1. unambiguously identify the members of the population,
2. line up all the members of the population, and
3. randomly select the sample from all the members of the population.

The first step is often the hardest. Certainly, it is easy to identify all the examinees who took the TOEFL in a given year. The Educational Testing Service has records of those examinees. However, language researchers often run into thornier problems like how to identify the population of all ESL/EFL learners in the world, or the more narrowly defined population of all ESL learners in the United States, or the still smaller population of all ESL learners at a particular school on a given day. Even when the population is very narrowly defined as in the third example in the previous sentence, unambiguously defining that population may be difficult because it can be a moving target (e.g., students transfer to other schools, new students arrive, some students are absent, etc.).

The second step, lining up the data for the members of the population, is also fraught with potential problems for several reasons: (a) because politics may intervene (e.g., the principal of one of the schools may withdraw her school from the study); (b) because records are often incomplete or inconsistent even when they do exist; and (c) because human-subjects rules at various institutions may preclude researchers from requiring participant cooperation.

Once the researcher gets past the first two steps, the third step is a snap. Randomly selecting the members of the sample from the population can be done by generating a random number for each member of the population (using, for example, the =RAND()

function in a computer program like Excel™), then sorting the data on those random numbers, and taking the desired number of members from the top of the resulting list to be the sample. Alternatively, random selection can be done using numbers from a hat, cards from a deck, a table of random numbers, and so on. The point is that any procedures can be used that ensure that each member of the population has an equal chance of ending up in the sample.

By using random sampling to select the members of a sample, researchers minimize the effects of their own conscious or unconscious preferences, biases, wishes, and desires on the results of the study. A large enough sample of randomly selected members is widely accepted by researchers to be approximately representative of the population from which it was taken (for more on random sampling in language research, see Brown, 1988, pp. 111–13; 2001, pp. 72–4; Mackey & Gass, 2005, pp. 119–22).

Stratified random sampling references particular strata within the population and randomly selects representative members of those strata from the population to form the sample. This technique involves three steps:

1. Clearly define the relevant population.
2. Pinpoint the important *strata* (i.e., the salient characteristics like gender, educational level, nationality, etc.) for that population.
3. Randomly select members from each of the strata in the population (as discussed above for simple random sampling).

For instance, if researchers wanted to study the population of all international students studying at the University of Hawaii, they might want to (a) identify all the members of this population, perhaps from records at the International Student Office, (b) pinpoint the important strata (in this case, perhaps gender and academic status), and (c) randomly select members from males and females to represent the gender stratum, as well as from the graduate and undergraduate students to represent the academic status stratum. The selection can be done in one of two ways, using quota or proportional approaches. *Quota stratified random sampling* would occur if the researchers randomly selected equal numbers of males and females, and graduate and undergraduate students, so that, for example, the resulting sample might contain 100 male graduates, 100 male undergraduates, 100 female graduates, and 100 female undergraduates. *Proportional stratified random sampling* would occur if the researchers randomly selected students from each of the two strata in proportion to the occurrence of those characteristics in the total population such that a population that contained 16% male graduates, 21% male undergraduates, 24% female graduates, and 39% female undergraduates would result in a sample with the same percentages. Using either type of stratified random sampling has the distinct advantage of allowing the researchers to use the identified strata as variables in their study.

Cluster random sampling is a form of selection “in which the sampling unit, the unit of selection, contains more than one population element, hence the sampling unit is a cluster of elements” (Kish, 1965, pp. 148–9). The *elements* are the unit of analysis, but the sampling units are *clusters* of those elements and the clusters are randomly selected. This technique also involves three steps:

1. Clearly define the relevant population.
2. Pinpoint the important *elements* (e.g., schools, classrooms, homerooms, etc.) for that population.
3. Randomly select clusters of those elements from the population (as discussed above for simple random sampling).

4 SAMPLING: QUANTITATIVE METHODS

For example, students might be the elements in a particular study, but the sampling would consist of clusters of students in homerooms. Thus, homerooms (clusters) would be randomly sampled, and each homeroom contains a cluster of students (elements) (Fink, 1995, pp. 14–17).

Quota cluster random sampling would occur if the researchers randomly selected equal numbers of students from each homeroom. *Proportional cluster random sampling* would occur if the researchers randomly selected students from each of the homerooms in proportion to their numbers in the total population, or used all of the students in the homerooms. Using either type of cluster random sampling has the distinct advantage of allowing the researchers to use the identified clusters as variables in their study.

Methods of Nonprobability Sampling

A *convenience sample* can be defined as the selection of objects of study that happen to be readily at hand (e.g., the students in my class and in my friend's class). A sample of convenience is probably not a sample at all. Given that it can only be said to reference itself, and cannot logically be said to represent anything larger than itself, a convenience sample would probably more appropriately be labeled a population. While a sample of convenience may be *ecologically valid* in the sense that it *is* the environment of interest to the particular teacher, generalizing beyond such a sample would be irresponsible because the sample *is* actually the entire population to which the results can be generalized.

Ordinary *stratified sampling* references particular strata but does not use random selection to sample from the strata. Instead, *quota* or *purposive* sampling strategies are typically used. *Quota stratified* sampling sets out to include certain numbers of persons or objects from particular prespecified strata. For example, a study using quota stratified sampling might nonrandomly include 10 male and 10 female Korean ESL students, 10 male and 10 female Korean EFL students, and 5 male and 5 female native speakers of English. In contrast, *purposive stratified* sampling involves using judgment to select members for the sample that are considered to be most representative of the population. For example, a purposive sample might be based on typical male and female students (the gender stratum) from each of the three years (the age stratum) in typical EFL classes in typical high schools in Korea. In the interest of credibility, the researchers should be prepared to defend these judgments of *typical* male and female students, *typical* EFL classes, and *typical* high schools.

Ordinary *cluster sampling* references particular clusters but does not use random selection to sample clusters or elements from the clusters. Instead, *quota* or *purposive* sampling strategies are typically used. *Quota cluster* sampling involves selecting certain prespecified numbers of clusters and elements from the population. For example, a study might include 10 students from each of 10 homerooms. In contrast, *purposive cluster* sampling involves using judgment to select clusters and elements for the sample that are considered to be most typical of the population. For example, such a sample might be based on all the students in three typical homeroom classes (one each from the first, second, and third years) at three typical high schools in a particular prefecture in Japan on a typical day. Again, in the interest of credibility, the researchers should be ready to defend their judgments of *typical* homerooms, high schools, and days.

Choosing the Right Sampling Strategy

One of the most common questions I get from graduate students doing quantitative research is, "What is the minimum sample size for my study?" That is a complex question to answer and, in fact, may be the wrong question altogether. Statistics books often cite the magic number 28 (or 30) as a rule of thumb for the minimum sample size to use, so students will

cite that number as a rationale for their relatively small sample sizes. This rule of thumb is not necessarily wrong. However, it is focusing on the *minimum number*, which may be the wrong way to think about this issue altogether. Why would researchers want to bet their entire study, or thesis, or dissertation on the *minimum* sample size? I prefer to think in terms of the sample size that is necessary to create a sample that is (a) adequately representative of the population, (b) maximally serving the purposes of the research, and (c) large enough to find statistically significant results if they exist in the population.

A Sample Should Be Adequately Generalizable to the Population

The *generalizability* of a sample is the degree to which it represents the total population, and similarly the generalizability of the results of a study is the degree to which the results based on the sample can be said to represent the same phenomena in the population.

If simple random, stratified random, or cluster random sampling have been used, and the sample is large enough, the researcher should have no doubts that the sample represents the population. If the researcher has doubts, then the sampling procedures need to be carefully examined and perhaps modified, or the size of the sample(s) should be enlarged, or both. Another way to look at this issue is that researchers should be as critical of their own research as they are of studies done by other researchers. That is, researchers should ask themselves if they would feel that the sample was large enough to be generalizable if this were another researcher's study.

A Sample Should Maximally Serve the Purposes of the Research

Another question related to sample size is the relative number and size of strata or clusters, which must be decided based on which type of sampling best serves the purposes of the research. If the population has fairly heterogeneous strata or clusters, either stratified or cluster random sampling may work better than simple random sampling, especially in cases where simple random sampling would result in too few members in each stratum/cluster, or would produce strata/clusters with markedly unequal sizes. This is especially true in cases where the strata/clusters will be used as variables in the analysis. However, if the sample is likely to be relatively homogeneous and fairly large, and the population strata/clusters will not be used as variables, simple random sampling would be the better choice because it is easier to use and generalize. Similar issues arise with selecting from among the nonrandom convenience, stratified, or cluster samples.

A Sample Should Be Large Enough to Find Statistically Significant Results if They Exist in the Population

The *power* of a statistical test (like a correlation coefficient, *t* test, etc.) "is the probability that it will lead to the rejection of the null hypothesis, i.e., the probability that it will result in the conclusion that the phenomenon exists" (Cohen, 1988, p. 4). Thus the *power* of a test indicates the degree to which researchers are likely to find a statistically significant correlation, mean difference, and so on, if the correlation or mean difference in fact exists in the population. If a study does not have sufficient power, one way to increase its power is to increase the sample size. Fortunately, the power statistic can be used to estimate how much larger the sample should be to achieve *X* amount of power (see for example Cohen, 1988; Kraemer & Thiemann, 1987; Dattalo, 2008).

So how large a sample is necessary to be large enough? On the one hand, it is safe to say that a large sample (relative to the population size) is likely to be more representative of the population than a small one. Clearly a sample of 9,999 out of a population of 10,000 ESL students is likely to be more representative of the population than a sample of 1000, or 100, or 10. In addition, samples that are selected in a manner appropriate for the research

being conducted are more likely to produce appropriate subsample sizes for any strata or clusters of importance to the research design. It is also a fact that larger samples tend to provide more statistical power than small samples. Thus, the researcher is more likely to find statistically significant results (if they exist in the population) if the sample size is large. On the other hand, because of politics, insecure administrators and colleagues, human-subjects rules, general human perversity, and so forth, data are often very difficult to collect in large numbers. So what is a researcher to do? I would argue that good researchers tend to ferociously focus their efforts on this sample-selection stage of their research, and get the largest sample they can practically obtain because they recognize the crucial importance of sampling to the quality of their eventual research results.

The Effects of Murphy's Law on Sampling

In addition to all the potential sampling problems discussed above, other issues may arise that can lead to less than ideal samples, especially when the objects of study are people. First, human-subjects requirements may lead to samples that are based on volunteers, who may have characteristics that make them unrepresentative of the population. Second, some participants may drop out of the study halfway through, and thereby affect the characteristics of the remaining sample (i.e., making it unrepresentative of the population). Finally, some members of the sample may produce incomplete data by not answering some questions, test items, and so on, which may in turn necessitate dropping them from the sample. These are all problems that researchers must plan for with the goal of minimizing their effects on the resulting sample.

Sapir, Edward

FRANS GREGERSEN

Edward Sapir (1884–1939) was born in Lauenberg Pomerania, the son of Lithuanian Jews. The family moved first to England and later to New York, where Sapir grew up. He studied with Franz Boas at Columbia University and was profoundly influenced by him. Sapir had a career which took him to Ottawa (1910–25), Chicago (1925–31), and finally Yale as Sterling professor of anthropology and linguistics. Sapir was one of the greatest researchers within the field of American Indian languages and a general linguist of major importance.

Sapir's importance for applied linguistics lies in his seminal writings within the psychology and anthropology of language and in his fathering of the so-called Sapir–Whorf theorem of linguistic relativism. Sapir is one in a long line of researchers (which may be traced at least as far back as Wilhelm von Humboldt) to contemplate the idea of extreme particularism (as opposed to universalism). Where universalism stresses the universal character of language and hence the many similarities between the various languages, particularism in its many guises will invariably focus on the differences and, in particular, on what these differences might mean to language users. In one of his papers, Sapir formulates the idea as follows:

Human beings do not live in the objective world alone, nor alone in the world of social activity as ordinarily understood, but are very much at the mercy of the particular language which has become the medium of expression for their society. It is quite an illusion to imagine that one adjusts to reality essentially without the use of language and that language is merely an incidental means of solving specific problems of communication or reflection. The fact of the matter is that the “real world” is to a large extent unconsciously built up on the language habits of the group. No two languages are ever sufficiently similar to be considered as representing the same social reality. The worlds in which different societies live are distinct worlds, not merely the same world with different labels attached. (Sapir, 1929, p. 209)

We find here a number of themes which would keep recurring in later discussions: the distinction between the objective, external world and the subjective one, mediated by the “language habits” of a particular society. Notably, the word “culture” does not occur, rather the worldview (“distinct worlds”) so dear to von Humboldt is alluded to.

By formulating an idea which could be pursued as an extreme form of particularism coupled with a stress on the linguistic representation of a social reality, Sapir has become the father of discussions of linguistic constructionism and incommensurability, be it in translation between languages or paradigms (Kuhn), in bilingualism, or in communication between communities which use languages belonging to different linguistic families. The idea, though mind-boggling, is simple: If we live in distinct worlds because our linguistic habits make us see our worlds differently, then we can never (fully) understand one another. Yet, in the New York where Edward Sapir grew up, very many people were at least bilingual, spoke languages which were different, and still lived at least in the same city and went to the same universities. The question then becomes: How different do language structures have to be for them to be, or imply, different worlds? Sapir's student Benjamin Lee Whorf formulated an answer in his distinction between Standard Average

European and the American Indian languages (the prime object for both Sapir and his pupil).

Sapir's ideas have been influential in several areas:

The study of language acquisition: Language habits are acquired along with language structure. Accordingly, theorists of language acquisition like Dan Slobin have contributed decisively to creating new answers to the Sapirian questions by looking at 'thinking for speaking' instead of a simple influence from language upon thought.

In the study of translation: Incommensurability of worldviews will always be the extreme end of the scale leading from perfect translatability via the situation where a translator has to create a whole new style in order to accommodate both the *écriture* and the language habits of a particular writer in another language, and to the end point of perfect impossibility of communicating a distinct idea in a language which does not know or accept that idea. Take the alleged violent form of communicating aggressive offense, for example, in some cultures and try to translate that into cultures that do almost anything to preserve the other's face!

In the study of literacy, Sapir's early recognition of the psychological reality of the phonemic contrasts has had some importance, and in the so-called code theory of Basil Bernstein's sociolinguistics, Sapir is explicitly referred to as creating the missing link between language and subcultures. Note that here we are dealing with distinct linguistic practices within the same nation-state (viz. the UK).

But Sapirian ideas have of course mainly been pervasive in anthropological linguistics: What do the typological, grammatical, and lexical differences between the language studied and the language in which the results are formulated really mean? In this sense, the Sapirian question is tied not only to cultural relativism—the idea that all languages are equally valuable, equally complicated, equally developed, although they differ in many ways—but also to epistemological relativism: If two ideas are formulated in different languages (and language may here be taken quite broadly as distinct practices within the same language system), we also have the idea of the incommensurable Kuhnian paradigms of the theory of science. The two ideas may not be compared (and thus evaluated) since there is no common ground to stand on.

Sapir's legacy within linguistics proper has been somewhat obscured by the fact that he died young and that his colleague Leonard Bloomfield became a major influence instead, but Sapir's brilliant insights continue to thrill and fascinate researchers within the cultural sciences. His collected works are published by De Gruyter.

Schachter, Jacquelyn

TEJ K. BHATIA AND WILLIAM C. RITCHIE

Dr. Jacquelyn Schachter contributed extensively to pioneering basic research on second language acquisition (SLA) in the 1970s and 1980s as the field was becoming independent of its previous role as a subsidiary to language teaching. In addition to her research, Schachter contributed to the expansion of the field by extensive editing of volumes of collected papers, conference proceedings, and periodicals.

Schachter was educated at the University of California in Los Angeles, USA, receiving her BA, MA, and, in 1971, her PhD at UCLA. Soon after she earned her PhD, she became a faculty member at the American Language Institute of the University of Southern California, also in Los Angeles. In the early 1990s, she left Southern California to become a member of the faculty of the Department of Linguistics at the University of Oregon in Eugene, Oregon.

Schachter's work on the presence or absence of subadjacency, a principle of universal grammar (in the sense of generative grammar), in the grammars of adult second language learners (Schachter, 1989, 1990) is, perhaps, her most important and best known work. Subadjacency limits the movement of elements (such as question words) within sentences in the grammars of adult native speakers and is claimed to be innate in the child language learner—as are all principles of universal grammar (UG). The question that Schachter investigated was whether this principle remains in force in the adult second language learner or whether there are critical or sensitive periods during which learners develop grammars that include principles like subadjacency but before which and after which they do not. Schachter studied native speakers of languages that lack rules that move question words either entirely (as Korean does) or to a large extent (as Chinese and Indonesian do). Schachter interpreted the results of these studies as showing that the grammars developed by adults in these cases do lack the principle and that there is therefore a sensitive period for the acquisition of grammars that include subadjacency and that adult second language acquisition is therefore incomplete with respect, specifically, to the subadjacency principle. This conclusion thus supports her general incompleteness hypothesis (Schachter, 1990), which states that second language acquisition in adults is incomplete with respect to the operation of at least one principle of UG—that is, subadjacency—and perhaps others as well.

In addition, she and a former student, Dami Lee, published important work on the conditions, universal in some form in the grammars of all first languages (hence, argued to be innately or genetically determined), that specify what noun phrase(s) in a sentence can be the antecedent of a reflexive form (like *himself*) or a pronoun (like *him*) in order to see whether or not these same conditions apply in adult-acquired second languages (Lee & Schachter, 1997). The study, they report, is a refinement of earlier studies bearing on sensitive periods in which participants were tested as adults and differentiated according to their first serious exposure to the second language; instead, Lee and Schachter tested participants in five age groups (who were putatively younger than the sensitive period or within the sensitive period or beyond it) as they were in the process of learning the second language, having (in the general case) arrived in an English-speaking environment three years before the study. The participants in the five groups show different profiles for the conditions on antecedent-reflexive pairs and antecedent-pronoun pairs, indicating that

the putative sensitive periods for the two conditions differ from each other. On the basis of these results, Lee and Schachter argued their multiple sensitive periods hypothesis, which claims that the sensitive periods for different principles of UG may differ, thereby requiring recognition of the possibility that there may not be just one sensitive period for grammar acquisition *in toto*, but that there are multiple sensitive periods.

Schachter published a number of important overviews of research in the field from the late 1980s to the mid-1990s. In Schachter (1988), she reviewed work that casts doubts of various sorts on UG as a sufficient account of the adult's capacity for second language acquisition. In Schachter (1996a), she argues that a general notion of learning may give a better account of the process of SLA in some respects than the notion of "triggering" that had been proposed within the generative framework. In Schachter (1996b), she reviewed the full research literature bearing on the presence/absence of critical or sensitive periods for language acquisition and their consequences for adult SLA and argued for the existence of what she referred to as "windows of opportunity" for the acquisition of (second) languages during which the learner is sensitive to input that determines the presence of principles of grammar in the grammars that result from adult SLA and after which he/she is not. These were, of course the "sensitive periods" of earlier and later work.

In earlier work on research methodology—in fact, Schachter's earliest publications—she dealt with the issue of whether or not the practice of error analysis—that is, the identification of the learner's errors as being determined by the nature of his/her native language or by general properties of language development—provides a significant account of the learner's knowledge of the second language. In a classic study (Schachter, 1974), she collected relative clauses in the written output of students of L2 English whose L1s had relative clauses that resembled those in English with respect to order of head noun and relative clause (native speakers of Arabic and Persian) and those of students whose L1s differed from English in order (Chinese and Japanese). She found that the Chinese and Japanese students produced significantly fewer errors in their English relative clauses than the Arabic and Persian students, but that the Chinese and Japanese students produced significantly fewer relative clauses—in effect, *avoided* producing relative clauses in English—than the Arabic and Persian students did, hence showing for the first time that in some cases avoidance is a clearer effect of L1–L2 difference than number or type of error. Connecting her basic research with the classroom—as she often did—she subsequently coauthored an article (Schachter & Celce-Murcia, 1977) in which the pitfalls of using error analysis as a basis for teaching are examined.

She also worked on the phenomenon of language transfer. This work includes both an empirical study (Schachter & Rutherford, 1979) and a theoretical proposal (Schachter, 1983). In the first-named work, she and her coauthor argue that the overproduction of existential sentences in the L2 English of L1 speakers of Chinese and Japanese is a consequence of the topic-prominence of these two languages as opposed to the subject-prominence of English. In the second-named paper, Schachter proposes a new account of the notion of transfer based on notions of hypothesis testing and concept formation from the literature of cognitive psychology.

Another area of research methodology addressed by Schachter is the use of learner grammaticality judgments or intuitions as evidence for or against specific hypotheses about the learner's underlying knowledge of the L2. Schachter, Tyson, and Diffley (1976) argue for a third type of judgment (in addition to "grammatical" and "ungrammatical") in characterizing learner judgments—namely, "indeterminate." Schachter and Yip (1990) provide evidence showing that one must consider processing (performance) factors as well as the learner's grammatical competence in explaining learner judgment.

Variability is a prominent feature of the learner's performance in the second language and Schachter (1986b) addresses four possible sources of this phenomenon: (a) the situation

in which a given utterance is produced, (b) utterance processing, (c) the language itself, and (d) the analyst him/herself.

Finally, Schachter (1998) critically examines methodological issues in three areas of SLA research: approaches to the study of SLA phenomena from the point of view of linguistic theory, the conditions under which second languages are learned, and the role of attention in SLA.

A crucial issue both in the theory of second language acquisition and in language teaching is the nature of the linguistic input that is available to the learner in the process of acquisition; and a number of different claims have been made about this central factor in SLA. Schachter (1986a) discusses three different approaches that have been taken to the question of what the input to a second language learner is and considers the value of each in arriving at an account that will contribute to our understanding of the phenomena of SLA.

Turning now to Schachter's more direct contributions to classroom practice, both of her works in this area (Schachter, 1981, 1991) are concerned with providing corrective feedback to students when they produce errors in the classroom. After briefly recounting the kinds of corrective feedback teachers used at the time, the first publication suggests a set of hand signals that can be used to indicate to the student what kind of error he/she had made, thus avoiding the necessity for interrupting the class to provide a verbal correction. The second work is also concerned with corrective classroom feedback, though from a slightly more theoretical point of view. Since corrective feedback constitutes "negative evidence" for the learner—that is, evidence that certain utterances in the second language are ungrammatical and it has been found that a child acquiring his/her first language does not make use of such evidence in learning their first language, the question arises as to whether adult second language learners make use of such evidence. Schachter notes that results of the basic research on this important practical issue are unclear and expresses the hope that the issue will be resolved in the future.

As noted above, in addition to the publication of basic research and overviews of the field, Schachter has contributed considerably to the expansion of the fields of TESOL and SLA research by coediting two very important volumes of readings, Robinett and Schachter (1983) and Gass and Schachter (1989) as well as a book series for Lawrence Erlbaum Associates entitled *Second Language Acquisition Research: Theoretical and Methodological Issues*. She was also the editor of the conference proceedings for the international TESOL conferences of 1978–80 and the editor of the *TESOL Quarterly* from June of 1978 to 1982.

As is clear from the above, Schachter's scholarly work focused on basic research in SLA. Nonetheless, she never lost sight of the relevance of this work for application to the resolution of pedagogical issues. Schachter writes (1993), "We need to create a mindset in which both teachers and researchers view classrooms as laboratories where theory and practice can interact to make both better practice and better theory" (p. 181).

Schiffrin, Deborah

ALEXANDRA JOHNSTON

Introduction

Deborah Schiffrin has been a professor of linguistics at Georgetown University in Washington, DC since 1982. She has also taught at the University of California at Berkeley. She lives in the Washington, DC area with her husband and two children.

Her areas of expertise include sociolinguistics, pragmatics, and discourse analysis, and her research interests cover a broad array of topics in language in interaction, including narrative analysis, contrastive approaches to discourse analysis, grammar in interaction, language and identity, and discourse and history. She has made groundbreaking contributions to the study of discourse markers (Schiffrin, 1987), discourse analysis, and narrative analysis. She has written four books, edited five books, and published over 51 articles and book chapters (her home page is at <http://www9.georgetown.edu/faculty/schiffrd/index.htm>).

Academic Background

Deborah Schiffrin (1951–) was born and raised in Philadelphia, Pennsylvania. She completed both her BA and MA in Sociology at Temple University in Philadelphia. Her first publications appeared in journals of sociology, such as a paper on the handshake (first published in *Semiotica* in 1974 and reprinted in 1981), and “Opening Encounters” (*American Sociological Review*, 1977). She then earned her doctorate in linguistics at the University of Pennsylvania in Philadelphia under the direction of William Labov. Her early influences included three very different scholars who have each had outsized impact upon the study of language: Noam Chomsky, the linguist who developed “transformational grammar”; William Labov, the sociolinguist who revolutionized research methods of sociolinguistics with his studies of dialectal features and everyday oral narrative; and Erving Goffman, the sociologist whose observations of the details of social interaction and the presentation of self found fertile ground in the field of discourse analysis.

The work of these three scholars prompted Schiffrin (personal communication, 1998, giving a narrative account of her career) to shift her research toward answering fundamental questions of language and social interaction: What do we say? How do we say it? What is its structure? What does it mean? And why does it matter? She thus turned her intellectual focus toward sociolinguistics and discourse analysis. Two members of her dissertation committee taxed her with separate challenges: William Labov urged her to use “sociolinguistic methodology to solve problems that have long vexed scholars.” Erving Goffman told her to “illuminate a phenomenon that would remain associated with [her] throughout [her] career” (Schiffrin, 1998, in personal communication to author). She fulfilled both charges with her dissertation study and subsequent publications on discourse markers and narrative.

Discourse Markers

Discourse markers are expressions like *well*, *but*, *and*, *so*, *oh*, and *y'know*. They are “one set of linguistic items that function in cognitive, expressive, social, and textual domains” (Schiffrin, 2001a, p. 54). Schiffrin’s study of discourse markers (1987) analyzed oral discourse obtained through sociolinguistic interviews using methods developed by Labov for use in variation analysis in order to account for the distribution of markers in spoken discourse. In demonstrating which markers occurred where, and why, Schiffrin attended both to the structure and meaning of the language used as well as the interaction (by showing what was going on at the moment of use within the interaction).

Schiffrin defined discourse markers as “sequentially dependent elements that bracket units of talk” (Schiffrin, 1987, p. 31). In other words, “nonobligatory utterance-initial items that function in relation to ongoing talk and text” (Schiffrin, 2001a, p. 57). She showed that discourse markers could be considered as a set of linguistic expressions drawn from word classes as diverse as conjunctions (*and*, *but*, *or*), interjections (*oh*), adverbs (*now*, *then*), and lexicalized phrases (*y'know*, *I mean*). She also proposed “a discourse model with different planes: a participation framework, information state, ideational structure, action structure, exchange structure” (Schiffrin, 2001a, p. 57). Her analyses “showed that markers could work at different levels of discourse to connect utterances on either a single plane or across different planes.” An example of the discourse marker *but* connecting several planes is reproduced below (Schiffrin, 2001a, p. 57).

Jack: [The rabbis preach,] “Don’t intermarry”
 Freda: [But I did– [But I *did* say those intermarriages
 that we have in this country are healthy.

Schiffrin states that

Freda’s *but* prefaces an idea unit (“intermarriages are healthy”), displays a participation framework (nonaligned with Jack), realizes an action (a rebuttal during an argument), and seeks to establish Freda as a current speaker in an exchange (open a turn at talk). *But* . . . thus has four functions that locate an utterance at the intersection of four planes of talk. (2001a, p. 57)

In addition to the functions shown above, discourse markers also display relationships that are local (between adjacent utterances), global, or both (across wider spans, structures of discourse, or both). Schiffrin shows they also add meaning to discourse (such as when *oh* marks information as “new” or “unexpected”). She concludes her analysis by specifying “conditions that allow a word to be used as a discourse marker: syntactically detachable, initial position, range of prosodic contours, operate at both local and global levels, operate on different planes of discourse.” (Schiffrin, 1987, p. 328, cited in Schiffrin, 2001a, p. 58). The key to discourse markers may be their multifunctionality on different planes of discourse that “helps to integrate the many different simultaneous processes underlying the construction of discourse, and thus helps to create coherence” (Schiffrin, 2001a, p. 58).

Following Schiffrin’s groundbreaking study of discourse markers, the first to thoroughly study the structure, function, and use of discourse markers in spoken discourse, the field of study has exploded. Scholars in linguistics and related fields have analyzed markers in various languages, their use in different interactive contexts, in language contact situations, and beyond (for a review, see Schiffrin, 2001a, pp. 54–5).

Further Contributions to Narrative Analysis and Discourse Analysis

Schiffrin's work on discourse markers came from a corpus of sociolinguistic interviews, primarily conducted with Jewish Americans in Philadelphia, during the course of which interviewees recounted hundreds of stories. These stories provided data for rich analysis, and Schiffrin's interest in oral narrative has continued from her earliest research to the present. She has written about arguments (1984, 1985, 1990), explored the sociolinguistic construction of identity (1996, 2006b), and demonstrated how events in life story narratives are retold for different purposes in different interactive contexts (2006a, 2006b).

Applying what she knew from analyzing naturally occurring stories in everyday interactions, Schiffrin widened her focus to other types of stories, including life stories and oral histories, which often combine elements of public and private discourse. A research fellowship from the Center for Advanced Holocaust Studies at the Holocaust Memorial Museum allowed her to transcribe a recording of the life story of a Holocaust survivor. She then examined how language use creates and reproduces identities at "textual, interactional, and cultural levels," in addition to relation-based identities (such as among family and friends: see, for example, "Mother and Friends in a Holocaust Survivor Oral History," 2002). The analyses of Holocaust life histories also included examination of change over time; that is, retellings of the same material at different times. She also studied terms of reference about place and experience in public discourse about the Holocaust, as well as of Japanese-American internment camps during World War II (Schiffrin, 2001b, 2001c).

Schiffrin also served as principal investigator for a National Science Foundation research grant to investigate topic-related variation, or the different ways that people indicate what they are talking about. The grant allowed her to explore her interest in the different levels at which topic can be identified, how topic intersects with information structure (such as how old and new information is indicated within the same sentence), and how information is foregrounded and backgrounded. In addition, Schiffrin explored her growing interest in functional approaches to language, such as how grammar "serves" the needs of communication. The research she undertook during this period not only produced articles on the functional and communicational aspects of specific words, such as the uses of *then* in temporal clauses, but also served to illuminate broad differences among different frameworks used to conduct discourse analysis, the subject of her second book, *Approaches to Discourse* (1994).

Approaches to Discourse traced how discourse analysis uses methods drawn from several other disciplines such as anthropology, sociology, philosophy, in addition to linguistics. Her book described and compared several approaches to the linguistic analysis of discourse, including speech act theory, pragmatics, conversation analysis, ethnography of communication, interactional sociolinguistics, and variation analysis. A second edition adds critical discourse analysis and narrative analysis to the broad methodological overview. Within each framework, Schiffrin presents original analyses of specific examples of language in use to illustrate the similarities, differences and overlaps among the approaches.

Schmidt, Richard

JANNY LEUNG

Richard W. Schmidt (1941–) is a versatile linguist whose primary research area is in the role of cognitive and affective factors, such as attention, awareness, and motivation, in adult second language acquisition (SLA) and foreign-language learning. He is also interested in both macro- and microsociolinguistics and the problems of learning and teaching difficult, less commonly taught languages.

Among his many contributions, Schmidt is perhaps best known for his work on the role of attention and awareness in SLA, an issue that is central to many theoretical and practical controversies in the field, such as mechanisms of language acquisition, the development of interlanguage and second language (L2) fluency, existence of implicit learning, and foreign language pedagogy. Schmidt claims that all learning requires attention and a low level of awareness (which he calls “noticing”), but not necessarily an intention to learn. This noticing hypothesis has been influential in SLA. He argues that awareness at the level of understanding is needed for explicit learning but not for implicit learning.

Schmidt has also written essays on wide-ranging areas including Arabic sociolinguistics, speech acts, advertising language, communicative competence (1983), interlanguage phonology (1987), and learner motivation (Schmidt, Boraie, & Kassabgy, 1996), and co-edited the *Longman Dictionary of Language Teaching and Applied Linguistics* (Richards & Schmidt, 2010).

Professional Life

Schmidt grew up in Massachusetts and obtained his BA from Harvard University in 1963. Before he pursued his postgraduate studies, he served as a foreign service officer for the US Information Agency, with assignments in Washington, Beirut, and Cairo. He then completed an MA and a PhD in linguistics from Brown University in 1971 and 1974. His doctoral dissertation was titled *Socio-Stylistic Variation in Spoken Egyptian Arabic: A Re-examination of the Concept Diglossia*. He lived in Rhode Island, Lebanon, and Egypt before settling down in Hawaii in 1976. He is currently professor in the Department of Second Language Studies and director of the National Foreign Language Resource Center at the University of Hawai'i at Manoa. He served as president of the American Association for Applied Linguistics in 2003–4 and received a Distinguished Service and Scholarship Award from them in 2009.

Ideas

Both the nativist tradition (focusing on universal grammar as a deep internal factor) and extreme empiricist approaches (such as connectionism, focusing on input as an external factor) to SLA seem to undermine the role of the learner's conscious mental processes. In recent years, more and more researchers have become interested in the cognitive requirements of learning, most notably attention and awareness.

DOI: 10.1002/9781405198431.wbeal1038

Schmidt (1995) sees attention and its subjective correlate, awareness, as nearly isomorphic. He characterizes attention as limited, selective, partially subject to voluntary control, responsible for controlling access to consciousness, and essential for action control and for learning (2001). Attention is required not only for the learning of meaning and structure; Schmidt (1993) argues that for pragmatic learning to take place, attention to the pragmalinguistic or sociopragmatic information is also necessary. His perspective is consistent with many SLA models. For instance, Pienemann and Johnston (1987) argue that the acquisition of developmental grammatical features is related to the learner's expanding processing space and the freeing of attentional capacity. Many psycholinguistic models also emphasize that cognitive factors such as perceptual salience and frequency, which affect attention, determine the ways in which the target language input is processed (e.g., Towell & Hawkins, 1994). Developmental progress is thought to be triggered by attention paid to the gap between what the learner can currently produce and what the target language is like. However, there are theorists (e.g., Carr & Curran, 1994) who argue that attention is important but may not be necessary for all kinds of learning.

According to Schmidt, consciousness—in the sense of “awareness” but not “intention” or “knowledge”—may be distinguished at three levels: perception, noticing (or focal awareness), and understanding (for a different conception of consciousness, see for example Block, 2005, who makes a distinction between phenomenal consciousness and access consciousness). Noticing is a subjective experience that can sometimes be operationally defined as availability for verbal report, subject to memory and metalanguage limitations. Only noticed information stands a chance of entering long-term memory.

The role of consciousness in language learning is an issue that sparked ample controversy. There are those who believe that accurate language production depends on a conscious understanding of the target language system, and thus consciousness-raising can facilitate language learning (Rutherford & Sharwood Smith, 1985). The opposite camp holds that much of language learning essentially takes place unconsciously (e.g., Seliger, 1983), and that learning without awareness is possible. And then there are those who argue that conscious and unconscious processes can both lead to “learning,” but they involve distinct mechanisms that result in different outcomes (e.g. see Krashen, 1981, who proposes that learning is conscious while acquisition is subconscious).

From an analysis of his own production data when he learned Brazilian Portuguese, Schmidt notes that other than words he had been taught explicitly, he produced only forms that he noticed people saying to him (Schmidt & Frota, 1986; see Tomlin & Villa, 1994, for a criticism of such diary studies, based on the observation that writing diary entries requires not only noticing but reflexive self-awareness). In Schmidt (1990) he reviewed the psychological literature on consciousness and argued that although subconscious processes are important for and common in language comprehension and production, subliminal language learning is impossible, and noticing is the necessary and sufficient condition for input to become intake. Mere exposure to input and subconscious processing are not enough to drive language development. Subliminal and blind-sight studies provide evidence for merely detection without awareness but not learning without awareness; evidence for implicit memory or learning by amnesiacs is seen as irrelevant to his noticing hypothesis because his claim is that it is *at the time of learning* that learning requires awareness (1995). Incidental learning is clearly possible and effective as long as task demands focus attention on what is to be learned.

Schmidt (1990, 1995) acknowledges that implicit learning, defined as learning without awareness at the level of understanding, remains a possibility. Although overall he feels that the evidence for implicit learning is weaker than often claimed, he thinks a case may be made for some implicit learning of foreign languages, especially when fuzzy categories, such as gender acquisition in French, are involved. He has later become more convinced

of the existence of implicit learning (e.g., “Both implicit and explicit learning surely exist,” Schmidt, 2001, p. 4). Schmidt holds that implicit learning is based on frequency counting via simple associative learning mechanisms, rather than unconscious rule abstraction. An example of how such associative learning mechanisms may work has been provided by connectionists (e.g., Rumelhart & McClelland, 1986), who found that a network of units can demonstrate rule-like behavior, but knowledge is represented only as association strengths distributed across a network. Schmidt (1990) regards the connectionist framework as appealing because it is consistent with the developing view that assumes a qualitative difference between conscious and unconscious processes.

Regarding the relationship between implicit and explicit knowledge, the noticing hypothesis, which is now a mainstream belief in SLA, incorporates the weak interface position, as it assumes that explicit knowledge may only indirectly affect the acquisition of implicit knowledge by focusing learners’ attention on the input features that are relevant to the target grammatical structure.

SLA researchers tend to agree that conscious rule application is not useful for fluent language performance. Extending from his interest in attention and language acquisition, Schmidt (1992) analyzes psychological mechanisms that underlie the development of L2 fluency, construed as a good ability to produce language in real time in an L2. He regards fluent speech production as automatic procedural skill that does not require much attention and effort. Certain aspects of speech production (e.g., phonological processing) may become automatic, but others, such as conceptual processing, continue to demand attentional resources.

Other than cognitive factors in L2 and foreign-language learning, Schmidt is also interested in socio-affective factors such as motivation. Using a questionnaire study involving 1,554 Egyptian learners of English, Schmidt et al. (1996) have identified three basic dimensions—affect, goal orientation, and expectancy—to motivation for learning foreign languages. These authors have also found that motivation is related to learning strategies and preferences. For instance, learners who scored high on the affective dimension tend to prefer communicative approaches in the classroom. In 2001, Schmidt edited a collection of essays on motivation with Dörnyei (Dörnyei & Schmidt, 2001). In this collection, Schmidt and Watanabe (2001) report the results of a survey of motivation on 2,089 learners of five different foreign languages (Mandarin Chinese, Tagalog, French, Japanese, and Spanish) at the University of Hawai‘i. Factor analysis reveals that the underlying factor structure consists of value, expectancy, motivational strength, competitiveness, and cooperativeness. Ethnic heritage also emerged as a factor. The motivational factors of value, motivational strength, and cooperativeness seem to affect strategy use and pedagogical preferences more strongly than others.

Schumann, John H.

BOB JACOBS

If the field of applied linguistics were a kitchen, John H. Schumann (born May 23, 1943) would be one of the master chefs. As one of the founding members of the field of second language acquisition, it is not surprising that his interest in language learning began early. He received both his BA and MA in Russian from Fordham University. Subsequently, he worked in the Peace Corps as a volunteer teaching English and then as the director of their Teaching English as a Second Language (TESL) program in Iran. In 1975, he received an Ed.D. in Human Development from the Harvard Graduate School of Education. In this same year, with this diverse background, he began his academic career when he joined the University of California at Los Angeles (UCLA) TESL/Applied Linguistic Program, which already had a well-established faculty (e.g., Clifford Prator, Donald Bowen, Russ Campbell, Evelyn Hatch, and Marianne Celce-Murcia). For 16 years (1985–2001), Schumann chaired the department, directing its focus on second language acquisition (SLA), assessment, and discourse analysis. During this time, the UCLA doctoral program became one of the preeminent applied linguistics departments in the world.

At UCLA, Schumann's research evolved in several identifiable stages. The early focus was on developing the pidginization hypothesis he had proposed in his dissertation, which suggested that an individual's restricted second language (or interlanguage) is a consequence of psychological distance from speakers of the target language (Schumann, 1976, 1978b). This was essentially a descriptive linguistic approach for characterizing the early stages of SLA. A logical extension of this hypothesis was to expand the perspective to include not only affective but also social factors, in what became known as the acculturation model (Schumann, 1978a, 1986). Acculturation was seen as a causal variable in SLA insofar as social-psychological integration into a target language culture could facilitate SLA. This second phase in Schumann's research went beyond linguistic descriptions of a learner's interlanguage and began an explanatory endeavor that opened up a broader view of language acquisition, one that eventually incorporated neurobiology.

This venture into neurobiology evolved out of his definition of applied linguistics. Rather than accepting the field as the narrow application of linguistic theory to language acquisition, Schumann adopted a much broader, eclectic perspective: applied linguistics is the application of diverse fields of inquiry (e.g., psychology, neurobiology, anthropology, linguistics) to language-related issues. Schumann thus encouraged his students to explore language from a variety of different perspectives, one of these being neurobiology. It was this kind of inquisitive, supportive environment that led to some of the early neurobiologically oriented publications about language acquisition (Jacobs, 1988; Jacobs & Schumann, 1992), speculative work that went well beyond the original neurofunctional foundations laid a decade earlier by Lamendella (1977). In this vein, Schumann founded the UCLA Neurobiology of Language Research Group. Part of this undertaking involved working with the well-known neuroscientist Dr. Arnold B. Scheibel of the UCLA Brain Research Institute. Together, they provided graduate students with a solid neurobiological foundation from which issues in language acquisition could be addressed. In this way, Schumann and his students outlined important areas of neurobiological research that could shed light on the language acquisition process.

This neurobiological stage of investigation was no minor undertaking for an established researcher attempting to tackle an entirely new discipline. Nevertheless, Schumann began intensively studying the intricacies of neuroanatomy and neurophysiology. Over several years, he developed sufficient expertise to extend his earlier links between affective factors and SLA. Although he initially underscored the amygdala's involvement in emotional processing, he recognized that the amygdala did not work in isolation (Schumann, 1997). He therefore proposed a tripartite stimulus-appraisal system that highlighted the interactions between the amygdala, the orbitofrontal cortex, and the body proper. This stimulus-appraisal system provided a neurobiological mechanism for an individual's preferences and aversions, which determine how an individual reacts in various language learning situations, and helps us understand their ultimate language proficiency in such environments. Working with his students, Schumann pursued a broad neurobiological account of learning from the perspective of language acquisition, resulting in a comprehensive overview where they clearly delineated fact from speculation and made insightful extrapolations from current brain research (Schumann et al., 2004).

This focus on the neurobiology of affect led to an evolutionarily based reexamination of how language is acquired. The resulting theory, known as the interactional instinct (Lee, Mikesell, Joaquin, Mates, & Schumann, 2009), suggests that linguistic structures in primary language acquisition are complex adaptive systems that emerge from conversational interaction, which is neurobiologically driven by affiliative reward systems in the brain (Schumann, 2007). Because the brain detects and learns verbal interaction patterns, grammar is epiphenomenal (i.e., a secondary consequence of the learning process), requiring no reliance on an innate universal grammar (Chomsky, 1965; Pinker, 1994). In this perspective, learning is viewed as being similar to a form of foraging (Schumann, 2001). As such, learning is a biological imperative in infants and motivates their interaction with conspecifics, resulting in the virtually inevitable acquisition of the primary language. In adults, however, there is a great deal more variability in SLA success, in part because of the affective and psychological factors previously outlined by Schumann (Schumann, 1978a, 1986, 1997), but also because of neurobiological factors (e.g., genetic variations and ontogenetic changes in receptor density) on which Schumann and his colleagues have begun to elaborate (Lee et al., 2009). The interactional instinct thus brings Schumann full-circle by allowing him to integrate his earlier social-psychological work on affect with more recent neurobiological investigations. This synthetic approach provides an evolutionarily plausible mechanism for the acquisition of the culturally inherited artifact known as language. Insofar as this area of inquiry is rich with possibilities, we can expect his future work will continue to integrate neurobiology, evolution, and language acquisition.

As representative as these academic foci are, several of Schumann's more "peripheral" publications actually provide a deeper understanding of his broad philosophical palate. In one of his earlier works, for example, Schumann (1983) drew parallels between quantum physics and SLA research, noting that researchers create the reality they investigate, and that philosophical flexibility is required to appreciate the aesthetic aspects of SLA theory building. Certainly, SLA has long been driven by competing theories. In this regard, Schumann (1993a) explained why the philosophical notion of falsification is problematic for evaluating SLA theories. In a different vein, Schumann (1993b) merged his interests in acculturation and neurobiology when he stepped outside SLA circles to explore the neural underpinnings of diversity in multicultural environments. Finally, in a return to philosophy, Logan and Schumann (2005) recently proposed that language is part of the symbolosphere (i.e., the nonphysical world of symbolic relationships). In this view, language is an emergent cultural artifact that arises from social interactions among brains and, as such, shares much with other cultural constructs (e.g., religion, law). What characterizes all of these

perspectives and his main research interests is a scholarly stretching of academic boundaries to advance our understanding of what language is, and how it is acquired.

Indeed, Schumann's academic and philosophical inquisitiveness is demonstrated by his interdisciplinary contributions to the field of applied linguistics. Not only has he been a prolific writer, he has also guided the careers of several generations of young scholars. On a more personal level, he applies this same omnivorous inquisitiveness to his culinary pursuits, often preparing elaborate dishes for colleagues as they discuss the latest research in the field. Indeed, it is in these moments when new ideas are discovered . . . that one can be sure there is a scholar in the kitchen.

Science of Language Policy and Planning

DAVID BRADLEY

Language policy and planning has a long history, but an explicit theoretical framework has only developed in the last 50 years. Usually the process is regarded in a unitary way, and called language planning, while the specific decisions involved are said to constitute language policy.

An early approach was that of Kloss (1969), which divides this into *status planning* and *corpus planning*. Status planning or language policy relates to decisions about the status and use that languages should have within a community. Corpus planning or language planning relates to the form and structure of languages: graphization of a written variety, standardization of its grammar, and modernization of lexicon. Status planning is often the role of governments and educational authorities; their decisions are frequently based on nation-building and other political and social agendas. Corpus planning may also be carried out by central authorities, though ideally this work is done by linguistically sophisticated experts and mainly based on established norms.

Another four-stage framework was devised by Haugen (1966): *selection*, *codification*, *elaboration*, and *dissemination*. Selection and dissemination correspond to status planning, while codification and elaboration are part of corpus planning. Selection is the choice of languages and their standard varieties. Codification is the graphization of the written form and standardization of grammar and vocabulary. This may involve creation, modification, or replacement of orthographies, similar decisions about grammar and vocabulary, preparation of standard grammars and authoritative monolingual and bilingual dictionaries. Elaboration is the expansion of the use of the language and modernization through additional areas of new vocabulary or new genres of literary and other uses. Dissemination is the educational, social, and other implementation of the codified and elaborated varieties, also sometimes called “acquisition” planning.

Both these models lack an essential component: evaluation; that is, the assessment of the success of policy and planning decisions and if necessary changes in their form or implementation. They also do not explicitly mention linguistic human rights, such as the right of minorities to mother-tongue education and access to government and national life.

A language policy is inherent in any political entity or institution, whether it is explicit or not. That is, every such entity has some official language or languages, even if this has not been proclaimed or legally instituted. These languages also have a standard form. Sometimes the form changes gradually through time, but more often the written and formal spoken variety becomes fixed for a longer or shorter period and thus gradually becomes archaic and less representative of current speech usage. This may sometimes lead to reform of the written variety, though such reforms are often contentious and tend to occur mainly after political changes. For much of recorded history, language policy has been a major tool of nationalism and building national identity, and language planning has often worked to unify nations around a single standard language, often at the expense of regional varieties and other local languages.

Sometimes the basis of policy decisions is explicit, as in the case of the former Soviet Union or the Peoples’ Republic of China, where non-Russian and non-Han Chinese nationalities were recognized based in part on their language, and standard varieties of

each language were selected based on being central, spoken by a large group, intelligible to other varieties and having an established sociocultural status, then codified in ways reflecting current political criteria. This meant the use of romanization in the Central Asian part of the Soviet Union in the 1920s and its replacement by Cyrillic in the mid-1930s, and in China in the 1950s the use of a romanization based on that codified for Chinese, then its replacement by Arabic-based scripts in the 1970s. Languages like Tajik and Uzbek had a 1920s romanization and a 1930s Cyrillic script in the Soviet Union, and a 1950s Chinese-based romanization and a 1970s Arabic script in China; of course in Afghanistan they continued to be written in Arabic script.

We lack explicit records for the political basis of early language policy and planning decisions, but the development of a standardized orthography, grammatical conventions, and vocabulary is a component of language policy; thus one might say that people like the Sanskrit grammarian Panini, the Alexandrine grammarians for Greek or Priscian for Latin were language planners who codified existing language norms and made them explicit. Similarly, the use and spread of Latin and Greek across the Mediterranean world two millennia ago was a status-planning process, as is the use and spread of Arabic in the Islamic world, and the use and spread of English in the modern world.

Language policy decisions are constant and dynamic, made every time one chooses to socialize children in a particular language, every time a teacher chooses a particular linguistic form, every time a government bureaucrat selects a language to address a member of the public, every time a government makes a proclamation, and so on. Political change may lead to linguistic policy changes, as in Greece where the diglossic high Katharevousa became associated with the military government and was eliminated from most official uses with its loss of power in 1974. Another example is the shift away from Latin in the Catholic Church, started in the mid-1960s but not yet complete.

In some countries, official or unofficial bodies have been created whose sole or primary purpose is to codify and standardize a national language. Their creation is directly related to other kinds of nation-building processes; many focus on lexicon. One early unofficial example was the Accademia della Crusca, established to maintain the purity of the Italian language in 1582. An early official example is the Académie Française, established by Richelieu in 1635, which continues to make linguistic decisions for French. For example, it recently coined a new word for e-mail, *courriel*, a contraction of *courrier électronique*, to replace the English loan *mél*. Many other countries have more recently established similar bodies, for example the Royal Institute in Thailand, established in 1933, or the Dewan Bahasa dan Pustaka (Institute of Language and Literature) in Malaysia, established in 1956 (Bradley, 1985). Some, like the Académie Française and the Royal Institute in Thailand, have developed into elite institutions whose membership is a recognition of status within the educated stratum of a society, not just for those working to standardize a national language. Others remain closer to their language policy and planning roots, and some remain government bodies.

Institutions formulating policy may develop gradually, as in China where the Association for Writing Reform of the Communist Party established in 1949 became the government Research Committee for Chinese Writing Reform in 1952, the Committee for Chinese Writing Reform in 1954, and finally the ministry-level State Language Commission in 1985. Policy bodies may also have their status and powers weakened, as in China where the State Language Commission merged into the State Education Commission in 2000.

Official language policy bodies usually make extensive corpus decisions, often piecemeal: orthography reform such as the elimination by the Académie Française of the circumflex accent from French (without consulting the rest of Francophonie), coining new words, fulmination against loanwords like *le weekend*, and so on. In some countries, the decisions of the policy-forming body are widely respected, implemented and used, while in others they are a source of amusement and are largely ignored.

One outcome of competing language policy decisions in different political entities is that a single language may become pluricentric (Clyne, 1992), having more than one norm in different countries. An extreme example of this is Chinese, where the 1956 character reform simplified nearly 40% of all characters, leaving Taiwan and Hong Kong using the traditional characters, with Singapore eventually changing sides in 1979 to the simplified characters (Bradley, 1992). We now recognize distinct Serbian, Croatian, and Bosnian languages, as a result of political separation; they were formerly all regarded as varieties of a single Serbo-Croatian language. Jespersen's aphorism, that a language is a dialect with an army and a navy, perhaps applies here.

In countries with or without an official language policy body, this role is also fulfilled by other government institutions: ministries of education, defense, interior, welfare, minority affairs and so on. "No policy" really just means no explicit legally codified policy with official status. The lack of an explicit policy may facilitate movements promoting a single national language, such as Official English in the United States from the 1980s (Crawford, 1992).

Linguists have contributed extensively to formulating and implementing national language policies in recent years, most notably the Australian Joseph Lo Bianco, who drafted a language policy for Australia (Lo Bianco, 1987), the first explicit language policy for any English-speaking country, led its implementation, and has also helped to draft policies for many other countries.

A major current issue for language policy and planning is linguistic human rights, such as early education through the mother tongue for minority groups, transitional to a national language (Tollefson, 1991; Hornberger, 2008). UNICEF and UNESCO have taken a leading role here. Another issue is the encroachment of covert status planning on corpus planning (Fishman, 2006).

Scientific and Technical Translation

SUE ELLEN WRIGHT

Even as products and procedures derived from science and technology are omnipresent in the twenty-first century, scientific and technical texts abound—from pharmaceutical inserts to wordless product assembly diagrams—designed one can assume to avoid the necessity of translation for international markets, but frequently incomprehensible in any culture. “Pure” scientific texts document leading-edge research. So-called “science writing,” on the other hand, distills scholarly texts written by experts for experts and popularizes them for the educated lay reader. The application of scientific principles to technological products and processes (sometimes called “technology transfer”) generates design documents, drawings, production and quality assurance manuals, and computer programs, all reflecting high levels of professional and technical expertise. On the side of the final customer, however, technological products frequently include instructions for nonexpert users. New inventions inspire countless patents, written in a special technical language melded with sometimes arcane and even archaic legal discourse. Similar hybrid varieties appear in official regulations governing the introduction of technology and science in areas affecting business, industry, public health, and the environment. Sci-tech Web pages and computer applications vie for international audiences. Difficulty levels range from the highly complex (e.g., specifications for a nuclear power plant) to the purposefully clear (“plain-text” instructions for using a medication). Any and all of these text varieties may under certain conditions require translation into one or many languages (Göpferich, 1995).

Defining Parameters for Sci-Tech Translation

Scientific and technical translation, especially if software localization materials are included, comprises the lion’s share of texts generated by the translation industry. If and when a translation service provider (TSP; or language service provider, LSP) considers the translation of any text, a number of translation parameters must be identified, either informally, or as part of a coherent project plan. In this context, a parameter is any definable factor used to customize a translation project. Many requestors do not know how to best meet their needs and those of their end users. As a consequence, the TSP will ask questions relevant to the parameters and integrate the answers into a blueprint for the final product and its relative quality. Some parameters may seem obvious at first glance, but it is not uncommon that significant errors and misunderstandings can occur if items are omitted (ASTM, 2006).

Language Pair or Pairs

Well-informed requesters usually know the language of a text and probably the desired translation target language as well. Sometimes, however, the TSP may have to determine the source language because clients cannot distinguish Catalan, for instance, from Spanish. The target language can be equally difficult—a request for Spanish for the South American market may ignore the fact that Portuguese will also be required if the intended audience includes Brazil. A request for “Belgian” or “Swiss” confuses nationality with language,

2 SCIENTIFIC AND TECHNICAL TRANSLATION

and failure to specify the desired language variety (en-GB [British English], for instance, instead of en-US [American English]) can result in a less useful target text.

Sociopolitical and economic factors determine translation source languages. Sci-tech translation tends to flow from language communities where new ideas and processes are invented and new products are produced. As a consequence, more texts are probably translated from languages such as English, Japanese, German, Korean, and Chinese because these languages are associated with strong research and industrial bases. Far more translation is also required for information-rich products like computer software, automobile, or airplanes than for maize or rice, where international users can be expected already to know the fairly simple instructions for how the product is used in the target culture.

Progress in language technology and cultural awareness supports multilingualism, particularly on the Web. Nevertheless, English continues to function as the language of high-level innovative science and as the source language for many scientific texts. This is true even when authors are not Anglophones because many articles are written by speakers of English as a second language or by international collaborative groups whose common scientific language is English. In situations (such as software localization) where interfaces and documentation will be translated into many languages, it is not uncommon for the text to be written in or translated into English first and for the other languages to be generated starting from English as a kind of pivot text (Ammon, 2001).

Subject Field

Most importantly for specialized texts, the subject field of the text must be identified. Science as such encompasses such fields as mathematics, astronomy, statistics, computer science, bioscience, chemistry, earth science, medical science, and the like (Wright, 2011). Technology involves the application of scientific observation to the creation of products and processes designed to benefit human endeavors of all kinds. Subject field classification can take place at a highly granular level, for instance description of brake bands used inside automotive transmissions (as opposed to other subfields involving automotive drive train components). Once a TSP has determined the subject field of a text (which may require the intervention of a language specialist), an effort is usually made to match the text to a translator competent in both the language and the subject combination.

Text Class

Texts are further classified according to the text type and variety (sometimes called “genre”). Text type concerns the intention or function of a text, that is, whether it is primarily informative, expressive, persuasive (sometimes called “appellative”), or perhaps interactive with the reader (“phatic”). Although one might expect sci-tech texts to be primarily informative, they may incorporate elements of advertising or encourage readers or listeners to adopt certain science-oriented strategies (for instance, adopting healthy lifestyles or promoting environmental “green” awareness). Materials prepared for certain populations may employ rhetorical devices designed to engage the trust and identification of the target audience in order to influence behavior (for instance, family planning information provided to immigrant populations with limited educational background). Translators working with such materials require highly sensitive familiarity with language usage, cultural attitudes, and even taboos in order to ensure that the target text conveys the desired intention. Text varieties reflect certain cultural expectations for the purpose and function of a text. The introduction above lists a range of text varieties. In this entry, “text class” represents the interaction of text type and text variety.

Terminology and Special Language

Knowledge of general language usage does not guarantee accurate special language competence because the rules and conventions applied to the selection of scientific and technical terms can vary considerably from language to language and subject to subject (Sager, McDonald, & Dungworth, 1980). Texts for translation also usually present novel information, so even experienced expert translators generally need to explore the terminology and content of each new text in order to document reliable equivalents in both languages. Sci-tech translators study so-called *background* and *parallel texts* (sources of information on the topic in the source and target languages, respectively) and frequently maintain terminological resources documenting lexical equivalents.

In addition to terminological information, translators are also concerned with text-related constraints, which can vary considerably from one language community to another and from one text class to another. In terms of style, the use of passive structures versus active verbs or the nominalization of verbs needs to reflect the expectations of the target audience. Even the way that individual cultures structure information can vary, such as the differences between Chinese and Western medicine, or even between German and Anglo-American classification of machine tools. Terms and concepts assigned to new technologies, like computer science, for instance, may be nicely parallel because contemporary researchers collaborate internationally. Traditional technologies, like steel making or agriculture, may, however, display vastly different term forms and concept ordering systems in different language communities.

Register and Situational Diversity

Subject field, text type, and text variety combine with language register to affect “situational diversity” (Sager & Nkwenti-Azeh, 1989, p. 19). Just classifying a text as medical does not necessarily mean that terminological or stylistic choices are cut and dried. The specific intention for the target text will determine choices on all levels. In many cases, the intention of the source text and that of the target text are hetero-functional (Nord, 1997). For instance, a text written for scientists in one language may actually be substantially rewritten as it is translated in order to produce a more popular science article—this is not uncommon when English scientific articles are popularized in another language. Learned terminology that is readily understood by experts may be explained or revised to appeal to lay readers, and strictly factual, informative presentation may be altered to add persuasive, entertaining, or phatic elements designed to engage a different readership. Even at the same relative level, science writing for a lay audience in English may sometimes be more serious in tone and less entertainment-oriented than science writing in German, but nevertheless, there are significant differences in style between publications—an article on the same topic written for *Wired* will be styled differently than one appearing in *Scientific American*.

The same medical topic may be reworked multiple times in order to present information to research experts, medical practitioners, educated patients, or uneducated patients with limited reading abilities. Register and the presentation of ideas may be carefully modified to accommodate cultural prejudice or the age and experience of a particular target audience. There are other ways that register plays a role. Regulations may require that pharmaceutical instructions printed on the outside of a medication package, which are extremely important for the user to understand, are written in plain language. In contrast, extensive fine-print inserts that are sometimes included inside the packaging are frequently technical and not all that accessible to the average reader. The way such materials are written or translated may even be prescribed by consumer-protection legislation in some countries and not in others. Such legal restrictions may also affect material safety data sheets, documentation for clinical trials, and other standardized reports and specifications.

Relative Translation “Quality”

Literary translators may choose to translate only texts that are well written in their source languages. Sci-tech translators rarely have this option. Scholarly books and journal articles, as well as textbooks, may be well vetted, and some science and technical writing is produced by trained technical communicators. A growing body of technical texts (aeronautical and automotive engineering, for instance) and texts for localization are often carefully prepared with translation in mind. These high-quality texts may even be written using controlled language, thus ensuring consistent terminology and rigorous style (Controlled English, 2007). Unfortunately, many other texts are of very poor quality, so much so that translators often strive to improve the target text.

There is no absolute set of criteria for determining the quality of a completed sci-tech translation. In industry, large quantities of scientific and technical material are translated using machine translation to produce so-called “indicative translations.” Sometimes brief synopses are created by less-qualified translators when there are too many texts to process and too few expert professionals, especially in less common languages. Both these activities can result in *gisting*, a style of translation that gives a notion of the content of the original without promising perfection. Such translations can be used for the purpose of triage, giving users an idea of which out of many texts should be given greater attention, or perhaps which segment of a longer text should be translated.

By the same token, other translations may be subject to very stringent quality analysis, and the assessment of the final product will reflect not just the abilities of one translator, but rather the experience and dedication of a whole team of experts. Many texts, such as computer interfaces or Web pages, must function in a way that is identical to the function of the original text, which means that they must be processed carefully using computer-assisted translation (CAT) tools that preserve or even adapt the functional elements of the text to ensure performance. Quality issues are reflected not only in the text itself, but also in layout and presentation in whatever medium is required. Ultimately, quality is measured in terms of requester expectations as reflected in the parameters specified in the project plan.

Scollon, Ron

NAJMA AL ZIDJALY

Introduction

Ron Scollon (1939–2009) was a prolific writer, social activist, and scholar who contributed multivariably to the study of language in (inter)action. Scollon is the author and editor of 17 books and over 90 essays, articles, and reviews on child language acquisition, intercultural communication, literacy studies, anticipatory discourse, mediated discourse analysis, and public discourse, with a special focus on native Alaskan languages and Asian interethnic communication (much of his research is coauthored with his partner Suzanne Wong Scollon). Scollon was also a founding editor (for North America) of *Visual Communication*, a cutting-edge journal on visual semiotics, and worked extensively as an intercultural consultant and in helping document a number of Athabaskan languages and cultures. Scollon's mediated discourse theory and its methodological framework nexus analysis advanced the field of applied linguistics by influencing the way discourse analysis is conceptualized and practiced. His vast theoretical contributions additionally have had wide application in education, public discourse, and professional and intercultural communication settings.

Academic Background

Ron Scollon received his BA in Japanese linguistics in 1971, his MA in linguistics in 1972, and his PhD also in linguistics (language acquisition, Athabaskan) in 1974, all from the University of Hawai'i. At Hawaii, Scollon also received training in Athabaskan linguistics from esteemed Athabaskanist—and a student of Edward Sapir—Li Fang-Kuei, resulting in Scollon collaborating with Li on the documentation of Dene Suline, Chipewyan (Holton, 2009). Once graduated, Scollon opted for an untraditional academic path—changing posts relatively frequently and doing a great deal of outside consulting work and freelance writing. This nonconformity broadened his academic and personal experiences, enabling him to develop his nonconformist ideas about language and the social space it occupies in reality.

After sporadically teaching linguistics courses at the University of Hawai'i from 1974 to 1978, Scollon took a post at the Alaska Native Language Center, University of Alaska at Fairbanks. While holding this position (1978–83), Scollon helped document the Alaskan Native language of Tanacross. To connect Alaskan faculty and students who lived across a 1,280-mile span, in 1981, the Scollons used the University of Alaska computer network to become the first in North America—perhaps in the world—to use e-mail conferencing to teach graduate for-credit literacy classes—four years prior to the invention of the Internet. Scollon additionally became the first to use the ethnography of speaking and sociologist Erving Goffman's interactional framework in an Athabaskan context to combat interethnic discrimination. These initiatives together with Scollon's (1980) pamphlet on Athabaskan–English interethnic communication, according to Holton (2009), have impacted Athabaskan classrooms tremendously, where his work is still used.

From 1983 to 1992, Scollon was an independent scholar, consultant, and lecturer on communication in organizations, media, intercultural communication, and language education, with a client list of over 50 governmental, business, and educational agencies in the United States, Canada, and Asia. In 1992 he joined the English Department at City University of Hong Kong, where his ideas about culture and communication culminated in the widely used *Intercultural Communication* (coauthored with Suzanne Scollon) that placed Scollon as a preeminent expert in the field. In 1998, Scollon became a professor of linguistics at Georgetown University, Washington, DC. In 2001, he launched his theory, mediated discourse analysis, which investigates a relationship that had perplexed him since his dissertation: that between language and human action. In 2005 Scollon retired professionally but continued being intellectually active.

Major Contributions

Scollon's academic journey (shared with Suzanne Scollon) has contributed to—and created—a number of academic fields within and beyond applied linguistics. The belief that language was a part of a whole and that the whole needed to be examined to understand the part of language (Norris, 2009) led Scollon to draw upon philosophy (Bhaskar & Nishida), psychology (Vygotsky & Wertsch), literary theory (Burke), sociology (Latour & Goffman), semiotics (Peirce & Hall), and even geography (Tuan) (Stockburger & Jia Lou, 2009).

Applied Linguistics

Scollon's contributions to applied linguistics fall into two categories: language acquisition and literacy studies. Scollon launched his academic career in 1976 with a book—based on his dissertation—on child language acquisition, *Conversations With a One-Year-Old*. Through a detailed case study, this book influenced the field of child language acquisition by introducing an innovative, interactional approach to language development. Scollon introduced the concept “vertical construction,” meaning one-word utterances that, as opposed to horizontal constructions such as sentences, are connected semantically but separated by pauses, intonation, and stress. This concept enabled Scollon, first, to demonstrate, contrary to then-held beliefs, the primacy of discourse development over syntactic development and, second, to showcase child agency in directing conversations, pointing consequentially to the centrality of interaction in language development. These original findings, according to Wright Fogle (2009), have impacted the field of first and second language acquisition ever since, evidenced by the continued use of many of his ideas, especially that of “vertical construction.”

Ron Scollon contributed further to applied linguistics in his 1981 book *Narrative, Literacy, and Face in Interethnic Communication* (coauthored with Suzanne Scollon), which examines the relationship between language socialization and literacy. This book is considered a classic of the academic field of new literacy studies, an interdisciplinary approach that views literacy as a social practice (Gee, 1996). Just as *Conversations With a One-Year-Old* changed how people conceptualized child language acquisition, *Narrative, Literacy, and Face* alerted researchers to the crucial role of home language socialization patterns in school literacy. It did so by showing how children from Arctic Village, Alaska were socialized into literacy at home differently than those in English-speaking homes, giving the latter an advantage over Athabaskan children at English-speaking schools. Literacy thus is argued to be a culturally situated social and political practice instead of a mere act of reading and writing. This new conceptualization of literacy—together with Scollon's numerous other works on literacy that reject the great divide between orality and literacy by arguing for

multiple types of literacies—has demonstrated the need to take into account cultural differences in language socialization—a concept that had previously eluded academics and educators alike (Zavala, 2009).

Mediated Discourse Theory

Scollon's biggest contribution to linguistics is his innovative approach of mediated discourse theory and its methodological framework, nexus analysis. Scollon has always been interested in language; his theoretical position, however, differed from mainstream discourse analysts: while others took the primacy of language as a mode of communication at face value and backgrounded everything else as context, Scollon spent a lifetime and many publications, such as *Mediated Discourse as Social Interaction* (1998), dissecting this "context" to unravel the exact role of language in human action. These investigations have led to the following truisms: language is not the primary mode of communication; language and action are mutually constitutive; actions are social (they create identities) and are always mediated by either language or other nonlinguistic mediational means such as using a computer or gaze; discourse, thus, is best conceived as either a form of action or a component of action—as a mediational means. This calls for a new approach to the analysis of discourse.

In *Mediated Discourse: The Nexus of Practice* (2001), Scollon names this new theory mediated discourse analysis (MDA), which shifts the unit of analysis from language to the mediated action, the moment social actors act, in real time, using various discursive and nondiscursive mediational means. MDA draws upon and links theories that centralize action (e.g., mediated action and practice theory) with theories that centralize language (e.g., critical discourse analysis and interactional sociolinguistics) and the dialectical relationship between discourse and action (e.g., conversational analysis and anthropological linguistics). In so doing, it provides a unifying starting point for discourse analysts and other communication-oriented scholars to understand language in conjunction with action.

Since linguistics to Scollon was a lens through which social issues can be addressed, he designed an ethnographic methodological guide called *Nexus Analysis* to accompany MDA (*Nexus Analysis: Discourse and the Emerging Internet*, 2004, coauthored with Suzanne Scollon). This "how to do socially active discourse analysis" manual postulates that to link discursive micro interactions with broader social issues, the analysis must be broadened to encompass not only moments of actions but also the histories, roles, and motives of involved participants and the mediational means they use. Only then can one truly uncover what really happens when people take action. With MDA and nexus analysis, Scollon challenges the limits of discourse analysis by providing a unifying theory and methodology that engages with discursive research that addresses social change—in so doing, he influences not only the field of discourse analysis but linguistics in general.

Intercultural Communication

Interethnic miscommunication was an interest of Scollon's throughout his career. Contrary to other linguistic anthropologists studying Native American languages, Scollon did not simply resort to "culture," a term he constantly problematized, as an explanation for the breakdown in communication between members of different communities. Instead he continued posing two questions: What is culture? And what is intercultural communication? These questions enabled him to illustrate interactionally how otherwise incomprehensible differences blamed on culture originate from discordant interactional styles and worldviews that affect interactions (Vail, 2009). In *Intercultural Communication* (1995, 2001), the Scollons replace the murky concept "culture" with the concept "discourse systems," which eliminates problematic overgeneralizations and oversimplifications. They also replace "intercultural

communication” with “interdiscursive communication” since cultures do not interact, but individuals—and discourses—do. Scollon (2002) in a published article argues further for conceptualizing intercultural discourse as a nexus analysis because it is an ongoing process of construction and negotiation among individuals—thus widening the analysis to encompass action, mediational means, and participants’ histories, roles, and motives because it is the only way to truly uncover the root of interethnic communication problems. In so doing, he establishes a theoretical framework for intercultural communication which, in addition to correcting many previous misconceptions, balances between theoretical inquiries and practical implications.

Public Discourse and Multimodality

Scollon’s interests extended beyond conversations, such as those between people of different ethnic backgrounds and experiences, to public discourse. In *Discourses in Place: Language in the Material World* (coauthored with Suzanne Scollon, 2003), Scollon initiates a new approach to teaching and researching language in the material world, arguing that we can only interpret the meaning of public texts like road signs, notices, and brand logos by considering the world that surrounds them. The Scollons’ theory of geosemiotics analyzes public discourse not only in terms of linguistic content but also ethnographically, in their physical context. This theory has important ramifications for semiotics, human geography, cultural anthropology, and linguistics; it illustrates that studying tools of communication as separate from their situated use is insufficient to understand communication. Additionally, it has led to a recent burst of dynamic multimodal research (e.g., Jones, 2005; Norris, 2007; Al Zidjaly, 2011). In contrast to Kress and van Leeuwen’s (1996) renowned visual semiotics framework which analyzes multimodal texts separated from situated use, these new models postulate that visual analysis must be grounded in social and multimodal contexts. In 2008, Scollon’s work in the area of public discourse culminated in an original book on how to do specifically public discourse analysis of public hearings.

So What?

Linguistics to Scollon was a tool to bring about social change by reducing ethnic discrimination and educational disparities; hence, his research was always driven by the question: So what? Scollon’s original approach to academic and social research has advanced the field of linguistics theoretically, analytically, and practically. Scollon’s work encourages scholars to broaden analytic contexts and question not only long-held beliefs but also their own motives and roles in creating change. His legacy is best expressed in these words from his last academic lecture (2009, p. 21): “we need to be more flexible in our thinking about the issues of social and political life that occupy so much of our time and analytical space.” The diverse career and innovative scholarship of Ron Scollon has opened a space for creative and flexible thinking, enabling others to continue to pursue the academic and activist paths he has forged in applying linguistics to the world.

Searchlinguistics

DAVID CRYSTAL

Searchlinguistics is the application of linguistics to analyze and alleviate the problems that arise when people try to provide or obtain information through online search. The term is not yet standard, but the problems are well recognized, and the demand for solutions is pressing. Several types of e-activity are involved, including the following:

1. online advertising, where the requirement is to ensure that ads which appear on a Web site are relevant, focused, and sensitive to the content of a page;
2. e-commerce, where the requirement is to obtain data about specific products in online catalogs;
3. search engine assistance, where the requirement is to receive accurate, relevant, and up-to-date hits;
4. automatic document classification, where the requirement is to find all files which deal with a specific topic or combination of topics;
5. Internet security, where the requirement is to identify undesirable activity on a site, such as pedophile activity in child chatrooms.

There has been variable progress in each of these areas, but all present difficulties arise out of the lack of a linguistically sophisticated frame of reference, as the following attested examples illustrate.

The Problems Illustrated

In relation to (1): A CNN page reported a street stabbing in Chicago, and the ads down the side of the screen said “Buy your knives here,” “Get the best knives on eBay.” A page on a German Web site described heritage tours of Auschwitz, and an accompanying banner ad from a German energy company advertised cheap gas. The advertising industry is keen to develop more sophisticated methods of targeting ads on pages in order to guarantee relevance and avoid insensitive misplacement. Companies are naturally upset when their ad agency places their products on irrelevant pages or in embarrassing locations. It harms their image and loses them sales.

In relation to (2): An inquiry for “shampoo” (where the inquirer meant “hair shampoo”), made via a search box on an online retail site, received a cluster of responses mainly about carpet shampoo and car shampoo. Another, to an online bookstore, asked for books by “David Crystal”; among the list of books received were some by the linguist and some by a Scottish poet with the same name. There was no way of determining which book belonged to which author. The confusion was compounded by the “further information” provided: “people who bought this book,” said the text accompanying a book written by the Scottish poet, “also bought the following . . .”—listing several books by linguists. With a really common name, such as various writers called John Smith, the possibilities for confusion are legion.

The retail industry is keen to develop more customer-friendly methods of interrogating online databases, but finds it difficult to anticipate all the factors which impede good

communication. An example is the inadequate specification of variant forms. A search (in Britain) for *mobile phones* on an electronic equipment retail site received the implausible response: “we have no mobile phones.” Repeated attempts using various lexical, grammatical, and orthographic variants (e.g., *mobile-phone*, *mobile phones*, *cellphones*, *cell phones*) all received the same negative response. Eventually it transpired that the only search term the software recognized was *cellular phones*. Faced with such e-incooperativeness, many people would not have the patience to continue their inquiry, and a sale would be lost.

In relation to (3): A request from a search engine for information about *apples* (where the inquirer had in mind the fruit) produced several million hits, but all the results on the opening page were about computers and the Beatles, including several results which were seriously out of date. An economist who typed in *depression*, expecting information about the financial climate, was swamped with results to do with mental health. Improving the relevance, accuracy, and up-to-dateness of search queries, without making the user do all the work (e.g., by adding extra search words or scrolling through pages of hits), is a continual goal of search engine companies, especially those trying to compete with Google. From the inquirer’s point of view, the aim is to save time and obtain the most meaningful hits. From a Web site-owner’s point of view, the aim is to achieve a high ranking for the site in any set of results.

In relation to (4): A lawyer failed to find all the documents in a database relating to a case in Bosnia and Herzegovina because he searched only for the name of the country in that orthographic form and failed to search for *Bosnia-Herzegovina*, *Bosnia & Herzegovina*, and other alternatives. Another found himself flooded with unwanted documents because a search for *New Mexico* also brought in material from Mexico, New York, and other locations containing the word *New*. In the first case, important information relating to the precedents in a case was not retrieved. In the second, much time was wasted, as the lawyers had to read through a great deal of material before discovering that a document was irrelevant.

In relation to (5): A newspaper article reported the story of a teenager ending up in a dangerous situation having agreed to meet offline an apparently innocent contact made during a chatroom conversation. The contact turned out to be a male predator. Several companies are now concerned to find ways of identifying potentially dangerous content within the discourse of chatrooms and social networking sites. The dangers have increased following the increased provision of content via cell phones. Parents at least had the opportunity to monitor online activity when this took place through the home computer, but this opportunity is lost when the contact is made directly to a child’s cell phone. Similar issues arise in relation to the use of the Internet to plan terrorism, fraud, or other criminal activities.

The Problems Analyzed

To a linguist, all these problems have one feature in common: they do not take into account the ambiguity inherent in the use of language.

In relation to (1), the software has found the lexeme *knife* appearing several times in the news report, assumed that this was what the page is about, and looked for the same word in the available ad inventory. It ignores the fact that *knife* = ‘weapon’ and *knife* = ‘cutlery’ are very different linguistic entities. If the software had looked at the linguistic context surrounding the word, it would not have made the erroneous identification: *knife* = ‘weapon’ would be accompanied by such lexemes as *murder*, *blood*, and *police*; *knife* = ‘cutlery’ would be accompanied by such lexemes as *fork*, *spoon*, and *plate*. A similar ambiguity lay behind the gas example: *gas* = ‘method of killing’ vs. *gas* = ‘source of domestic energy’.

In relation to (2), the various contexts in which the word *shampoo* appears were not distinguished because the inquirer had not anticipated the ambiguity by using a more

specific search term. In this example, the alternatives are easy to see, as *shampoo* is a concrete term with few senses. In the case of words which have many senses, or which are more abstract in meaning, such as *depression*, it is not always obvious how to express a search in such a way that all the unwanted contexts are excluded. In the case of the Amazon authors, the problem arose because of the lack of an appropriate authorial classification in terms of either biography or subject matter. In the *mobile phones* example, the factors being ignored were to do with British and American English, grammatical number, and orthographic conventions.

In relation to (3), once again the various senses of a word (*apple*, *depression*) were not being distinguished. Plainly the problems arose from the polysemic character of the words—in the case of *depression*, failing to separate the senses relating to the knowledge categories of mental health, meteorology, economics, and geology. It might be thought that simply increasing the number of search terms will improve the relevance of hits in relation to inquiries: this turns out to be not always the case. Because of the way search engines typically work, increasing the number of search terms can bring an increased diversity of results. More relevant results will be found, but they can be hidden within further irrelevant hits. And in any case, thinking up exactly which search terms produce the best results is not always easy. Adding *deep* to *depression*, for instance, will not resolve the ambiguity.

In relation to (4), we see the ambiguity problem in relation to place-names. A glance at any gazetteer will show that the same name (*Lancaster*, *Newtown*) can turn up dozens of times in various countries. The orthographic variation encountered in the Bosnia example is just one variable, made more difficult when accents (often ignored by the software) are part of the words. Not all searches can be made successful by the simple expedient of adding an extra locator (e.g., *Lancaster + UK*). For example, it is not a straightforward matter to frame a search so that it finds only entries on the state of *New Mexico* while ignoring all entries relating to the country of *Mexico*.

Ambiguity also arises in relation to (5), but in a different way, involving the pragmatic interpretation of sentences as well as the polysemy of individual words. All suspicious activity involving language is coded in some way. No terrorists, fraudsters, or pedophiles are going to openly declare their intentions in plain language. Rather, their meanings are expressed indirectly and the overall import builds up over a period of time. Any individual sentence, viewed in isolation, appears to be innocent. Only when viewed as part of a sequence with other sentences does a picture emerge of a hidden intention. In the case of pedophile activity, for example, the sentence *How old are you?* is innocent enough as a casual inquiry; but seen along with such other sentences as *Are you alone?* or *What are you wearing?*, a different linguistic profile appears. We need to distinguish between innocent conversations and those which, through their use of suggestive words and sentences, build up a suspicious pattern of discourse over time. Such analyses are not easy to make, however, for reasons that are nothing to do with linguistics. It is difficult to obtain samples of authentic data to analyze in order to provide norms. Applied linguists need to obtain clearance from the relevant authorities whenever they propose to engage in counter-criminal research, and this is never easy to obtain.

Directions for Research

The above examples suggest several directions for future searchlinguistic research.

A semantic approach is needed to describe the polysemy of lexical items, relate the senses to a knowledge hierarchy representing online content, and assess the contribution individual lexical items make to the semantic identity of an e-text. It is not enough to say that *depression* has the four meanings noted above; we must assign each use to the knowledge domain to which it belongs. *Depression* = ‘downturn in economic growth’ needs to

be assigned to “economics”; *depression* = ‘area of low pressure’ to “meteorology”; and so on. The amount of ambiguity presented by a lexical item also needs to be taken into account: an item such as *quarterback* makes a high-value contribution to the domain of “American football,” because it is rarely encountered outside this setting; when we see that word on a page, it is virtually certain that the page is going to be about American football. By contrast, an item such as *depression* is less predictive because it is used in four domains; and an item such as *country* has a very low predictive rating, because it can be used in relation to hundreds of domains (all the countries of the world, for a start). Once lexical items have been identified in this way, it is possible to build up lexical sets which specify the semantic content of a knowledge domain, and this can then be used to build a filter which will analyze the content of Web pages, as in the iSense and Sitescreen products developed by an e-advertising network (ad pepper media, 2008a, 2008b). These sets need to include high-frequency collocations, and they also extend the traditional remit of semantics, as proper names have to be included, in view of the fact that Web content contains many brand names, models, company names, logos, and other “encyclopedic” expressions.

A grammatical analysis needs to be made to ensure that all morphological and syntactic factors are taken into account, such as inflectional variants (*mobile phone(s)*) and compounding alternatives (*cellphone*, *cell-phone*, *cell phone*). Word-class tagging may be needed to distinguish homographs (*bear* verb vs. *bear* noun). And syntactic information is required whenever we need to refer to sentence structure in order to resolve an ambiguity. In advertising, for example, clients often want their ads to appear only on pages which say “nice” things about their product; they do not want their ads to appear on pages which say “nasty” things. To identify these different kinds of sentiment, lists of positive and negative lexemes must be compiled. Positive items in English would include *fantastic*, *best*, *wonderful*, *marvelous*; negative items *awful*, *terrible*, *disaster*, *bad*. But, in any review, we have to allow for the effects of negation: *her latest recording is by no means bad*; *his new book is not one of his best*. The positive meaning of a lexical item can be reversed by the syntactic context in which it occurs. A grammatical perspective is thus critical.

A sociolinguistic or stylistic analysis perspective is needed to ensure that lexical lists are truly comprehensive—for example, including formal and informal variants (*television* / *telly*, and the various kinds of slang), regional differences (e.g., American vs. British English, such as *color* / *colour*, *car boot* / *trunk*), and within-region alternatives in spelling, punctuation, and capitalization (*judgment* / *judgement*, *Bible* / *bible*). Stylistic issues also arise in relation to pages with figurative or rhetorical content, such as metaphor, irony, sarcasm, and other forms of expression where the language operates at different levels. We do not want a football report which happens to refer to players “sliding all over the pitch like ducks on an icy pond” to be classified as a page about ornithology. In this respect, poetry is likely to be the most difficult genre for a searchlinguistics to handle.

A pragmatic perspective is needed to take into account differences which arise out of the purpose of Web pages. Why does someone write a Web page? Is it to inform, to entertain, to persuade, to express extreme views, to titillate, to sell . . . ? The pragmatic purpose inevitably affects the linguistic character of the page: for example, pages intended to sell products will have their own lexical character (*your account*, *basket*, *special offers* . . .), as well as a distinctive graphical and functional layout, and pages with extreme views will typically contain a great deal of taboo language. More fundamentally, the digital medium is changing our notions of how texts are created, as illustrated by the multiauthoring of wiki pages. Indeed, the traditional notion of written text as having stability and determinate boundaries is called into question by sites (such as forums and chatroom interactions) where what we see can alter from one moment to the next (Crystal, 2010).

Searchlinguistics can never be a purely synchronic study, because the linguistic content of the Internet is time-sensitive. Each page is time-stamped, even though the date at which a page was brought into being is often not immediately evident. Searches give the appearance of being synchronic, though in fact they present simultaneously hits from different time periods. Disentangling the conflicts in the data (e.g., when a series of search results gives different population estimates for a country) is not always easy, and this problem is going to increase as the Internet archive grows.

A diachronic perspective is also essential in resolving the ambiguities mentioned above. New terms are constantly being introduced into a language, and they have to be added to the lexical sets; for example, in 1999 any set of lexical items relating to Iraq would not have included the phrase *weapons of mass destruction*—something which became necessary in 2003. Or, to take a more commercial example, as new models of automobile come on the market, their names and model designations have to be incorporated. The diachronic perspective also applies in retrospect. As more historical material becomes searchable, lexical sets devised for the present day need to be adapted to be appropriate to the earlier period. The lexical set for road vehicles devised for the 2000s, for example, is not going to work well when applied to a newspaper corpus relating to mid-Victorian English, with its *broughams*, *phaetons*, and *landaus*.

Searchlinguistics is in its infancy because the industry that it aims to service is in its infancy. It is an industry, moreover, which is rapidly evolving, as new technologies become available and present fresh challenges and opportunities. A complication is that this is a highly competitive industry which is continually “moving the goalposts,” as businesses strive to keep ahead of each other, so that it is hard for applied linguists to keep up (Crystal, 2008). For example, whatever strategies might work for Internet search on computers, these have to be adapted as Internet access becomes increasingly routine via cell phones. And fresh search problems are generated as the amount of text in a file reduces, as in the formal constraints imposed by Twitter (limited to 140 characters) or text messaging (160 characters), or on Internet pages where the content is predominantly visual, and analysts need to refer to the underlying metadata to obtain sufficient text to carry out any linguistic analysis at all. The way the data is coded also varies, so that it is not always easy to guarantee that a “scrape” of a page to extract relevant text will exclude unwanted material, such as search menus, help files, and programming formulas. For such reasons, searchlinguistics presents applied linguists with some of their most intriguing challenges.

Searle, John R.

JÚLIA BARÓN PARÉS

John Rogers Searle (1932–) has made an outstanding contribution to the philosophy of language. His work on the speech act theory, with the well-known *Speech Acts: An Essay in the Philosophy of Language* (1969), has been among the most influential in linguistics and applied linguistics, specially within the field of pragmatics. John R. Searle's work has also been recognized for his research on the philosophy of mind and social philosophy.

John R. Searle was born in Denver, Colorado, and studied at the University of Wisconsin from 1949 until 1952. He then attended Oxford University as a Rhodes Scholar where he studied under the influence of John Austin from 1952 to 1959. At Oxford University he obtained a bachelor of arts (1955), a master of arts (1959), and a doctorate in philosophy (1959). He is currently a Slusser Professor of Philosophy at the University of California, Berkeley.

During his career, John R. Searle has been a lecturer and a visiting professor at several prestigious universities in the United States and around the world and has obtained honorary degrees from universities across the world: the University of Belgrade (2009), the University of Turin (2000), the University of Bucharest (2000), the University of Wisconsin (1994), and Adelphi University (1993). He is an honorary professor at the Tsinghua University, Beijing (2007) and at East China Normal University, Shanghai (2007). He has been awarded with numerous prizes including the Puffendorf medal (Sweden, 2006), Mind and Brain prize (Italy, 2006), National Humanities medal (USA, 2004), Jovellanos prize (Spain, 2000), and the Distinguished Teaching award at the University of California (Berkeley, 1999), among other prizes and honors. Likewise, Searle has been president of the American Philosophical Association (Pacific Division, 1990) and he has been a member of the American Academy of Arts and Sciences since 1977. Most of his research has focused on the philosophy of language; he is specially known in the field of pragmatics for his work on speech act theory. Following John Austin's (1962) philosophy of language, speech act theory postulates that when communicating, people perform three types of acts: a *locutionary act*, an *illocutionary act*, and a *perlocutionary act*. In addition, Searle presented a taxonomy of speech acts (*representatives, directives, commissives, expressives, declarations*) which has been widely used in pragmatics.

In relation to the illocutionary force of speech acts, Searle also proposed the concept of intentionality in his work *Intentionality: An Essay of the Philosophy of Mind* (1983). Based on the illocutionary acts, intentionality was developed as, first, the speaker's objectives which lie underneath each speech act and, second, as the collective intent in social action rather than an individual act, which is the basis for the creation of social reality, as discussed in *Collective Intentions and Actions* (1990) and in *The Construction of Social Reality* (1995).

Searle's work has additionally focused on the philosophy of mind and consciousness. One of the most controversial contributions to the field has been the "Chinese room argument." This argument, which was approached in "Minds, Brains, and Programs" (1980), aims at raising the weaknesses of artificial intelligence. Strong supporters of artificial intelligence had previously claimed that it would be impossible to distinguish a machine from a person. As a response to this, Searle conducted the Chinese room experiment to demonstrate that even if computers have programs which may allow them to simulate native

speakers' answers that does not entail that computers are capable of understanding. As part of his work on the philosophy of mind, Searle delved into the philosophical debate about the dichotomy of consciousness and brain. With "Biological Naturalism" (2007) Searle claimed that consciousness actually exists and is a result of specific brain processes.

Apart from his contributions to the philosophy of language, mind, and social philosophy, Searle became involved in politics while he was in Berkeley. He joined the Free Speech Movement, a university political movement which fought for the students' rights and freedom, and which also claimed that politics should not be prohibited on the university campus. As a result, he wrote *The Campus War* (1971) in which he presented the political and social situation of that time, dealing with the possible causes which had led to the students' political reaction toward 1960s America and against the lack of free speech at university settings.

John R. Searle's work on the philosophy of language has had an immense impact on the field of pragmatics, with a major influence on interlanguage pragmatics and cross-cultural pragmatics. Searle's taxonomy of speech acts has been the most commonly used taxonomy in pragmatics in order to examine how different speech acts are performed in different languages and cultures.

As for interlanguage pragmatics, Searle's speech act theory has been the basis of numerous studies on how learners of a foreign or second language use and develop speech acts in the target language, both in the classroom and outside it. It is also important to mention that Searle's theories have also raised numerous criticisms, among them, the idea that Searle's theory of illocutionary acts is based on functional criteria (the use of complete sentences as illocutionary acts), while a speech act is actually a pragmatic feature that may be formed by a stretch of speech with a communicative function. In addition, his idea that the speech acts are semantically universal has been highly criticized, with numerous claims that these may actually vary with culture (e.g., Wierzbicka, 1991). Finally, Searle has also been criticized for overlooking the role of the listener in the interaction. However, Searle's concepts are still among the most influential in the field of pragmatics, his work is being translated into multiple languages, and his theories are still being applied, adopted, adapted, criticized, and investigated all over the world.

Second Language Acquisition and Gesture

GALE A. STAM

Introduction

A gesture as defined in the *American Heritage Dictionary: Fourth Edition* is “a motion of the limbs or body made to express or help express thought or to emphasize speech.” Today, gesture in its broadest sense of bodily movement is an accepted area of study in a number of disciplines that involve human thought, interaction, or expression such as cognitive psychology, psycholinguistics, anthropology, communication, dance, music, and recently second language acquisition (for examples of the breadth of gesture research, see the journal *Gesture* and the International Society for Gesture Studies at www.gesturestudies.com).

In order to understand gesture’s relevance for second language acquisition, it is necessary to know what different kinds of gestures there are, what their relationship is to speech and language, and what research has been conducted on gesture in second language acquisition. These topics are discussed in the next sections.

Gesture

Often when people think of gesture, the first thing they think of is a gesture such as the “okay” sign—a culturally specific gesture, an *emblem*, which differs in meaning from culture to culture. However, emblems are not the only type of gesture. Gestures can be arranged along a continuum in terms of their relationship with speech (Kendon, 1988). This continuum, named *Kendon’s continuum* in honor of Adam Kendon (McNeill, 1992, 2005), encompasses movements that range from gesticulation (spontaneous movements of the hands and arms that accompany speech) to sign languages:

Gesticulation→Speech-Linked Gestures→Emblems→Pantomimes→Sign Languages

Gesticulations (Spontaneous Gestures)

Gesticulations (spontaneous gestures or co-speech gestures) only occur with speech. They are synchronous with speech and often occur with elements of high communicative dynamism, that is, contrastive, focused, or new information (McNeill, 1992). In addition, their strokes tend to co-occur with prosodic peaks (Nobe, 2000). Gesticulations perform the same pragmatic functions as speech. These gestures and their co-occurring speech complement each other, where the gestures indicate an aspect present in the speaker’s thought, but not expressed through speech.

Gesticulations can be analyzed in terms of their semiotic properties, and several different classification systems have been developed for categorizing them. The majority of these are variations of David Efron’s original system of batons, ideographs, deictics, and physiographs. The various categories are not mutually exclusive, and gestures may fit more than one category at a time. Therefore, McNeill has recommended that gestures be analyzed

2 SECOND LANGUAGE ACQUISITION AND GESTURE

in terms of dimensions such as “*iconicity, metaphoricity, deixis, ‘temporal highlighting’ (beats), social interactivity*” (McNeill, 2005, p. 41), not categories.

According to McNeill, gestures that have iconicity represent concrete objects or actions, for example, a hand moving upward and produced at the same time as the word *up* is uttered while those with metaphoricity represent an abstract idea, for example, two hands holding an *idea*. This is not to say that the gesture with metaphoricity does not have iconicity as well. It has both dimensions: iconicity for a container and metaphoricity for an idea. This is why it is important to describe gestures in terms of dimensions and to look at their accompanying speech. Gestures with deixis involve points to entities in real or abstract space indicating location or time. Those with temporal highlighting (beats) consist of quick movements of the hand either back and forth or up and down in time with the speech rhythm. These occur at the metalevel of discourse and highlight information: they may introduce new characters and new themes, summarize action, and accompany repairs. Gestures with social interactivity indicate interaction between a speaker and a listener, for example, a speaker saying *What do you think?* and extending a hand toward a listener on *you think* for the listener to respond.

Gesticulations serve many functions and may serve several functions simultaneously as Stam and McCafferty (2008) have pointed out. Besides adding information that is not present in individuals’ speech, they may serve to lighten speakers’ cognitive load and improve their performance in other areas. They may help speakers organize spatial information for speaking and aid in the conceptual planning of speech. In addition, they may indicate transition in cognitive and language development. They may be used to retain turns during conversation and listeners may gesture to indicate to speakers that they are actively involved in the conversation. Finally, gestures may indicate speech-production difficulties and facilitate lexical retrieval.

Speech-Linked Gestures

Speech-linked gestures are similar in form to gesticulations; however, they differ in timing. They occur with speech, but they are not synchronous with speech. They fill a speech gap, a grammatical slot in the sentence, and their execution completes the sentence and produces what Tatiana Slama-Cazacu has termed *mixed syntax*, for example, “Sylvester went [gesture of an object flying out laterally]” (McNeill, 2005, p. 5).

Emblems

Emblems (or quotable gestures according to Adam Kendon) are gestures that can occur with or without speech. These gestures are conventionalized, translatable gestures whose meaning is well-known to all members of a cultural group. They are gestures such as the “thumbs up” gesture (fist with thumb up) or the Dutch gesture for *lekker* ‘tasty, yummy’ (flat hand moving back and forth roughly parallel to the head at a small distance, 1–2 inches from the ear). Many emblems go back to Roman times, and the same form may have various meanings in one culture, as well as different meanings in different cultures. Emblems are learned gestures and are, therefore, teachable.

Pantomimes

Pantomimes are gestures that occur without speech. These movements can depict objects, actions, or an entire story. Pantomimes are the types of gestures people make when they are playing a game like charades.

Signs

Signs are codified gestures that occur without speech, have linguistic properties (i.e., phonology, morphology, and syntax) and are equivalent to lexical words (McNeill, 2005). They form the basis of sign languages. There are two types of sign languages: primary sign languages—sign languages used in Deaf communities such as American Sign Language (ASL), and alternate sign languages—sign languages that develop in communities where speaking is impossible because of the task people are engaged in or taboos such as the sawmill sign system, monastic sign languages, and Australian Aboriginal sign languages (Kendon, 1988).

Speech, Gesture, and Language

Prior to the 20th century, gesture was primarily studied in two ways: from Roman times to 1700, as it related to rhetoric, that is, how gestures could enhance a speaker's presentation; and from 1700 to 1900, as a precursor of oral language for the information it could give about language evolution. It was not until 1941 that gesture began to be studied in a systematic manner in human interaction with the groundbreaking work of David Efron.

Efron compared the gestures of Southern Italian immigrants (speaking Italian) and Eastern European Jewish immigrants (speaking Yiddish) with those of assimilated Southern Italians and Eastern European Jews (all speaking American English) in the United States. He found that the Eastern European Jewish immigrants used primarily their forearms and hands as well as less gesture space than the Southern Italian immigrants and produced metaphoric gestures, whereas the Southern Italians used their entire arm and produced iconic or emblematic gestures. He also found that the gestures produced by the two assimilated groups had become more similar and more American in nature.

Although Efron's work opened the door for more research on body movement and gesture in the decades that followed (e.g., the work of Birdwhistell, Ekman, & Friesen, and Condon & Ogston), gesture was viewed as part of nonverbal communication or body language and paralinguistic, outside of language, by researchers. This perspective, however, changed in the 1970s with the work of David McNeill and Adam Kendon who independently proposed that speech and gesture are aspects of the same process.

While analyzing a speaker's speech and gesture in a filmed segment of discourse, frame by frame, Kendon found that the speaker's gestures and speech pattern were very much related, "as if the speech production process is manifested in two forms of activity simultaneously; in the vocal organs and also in bodily movement, particularly in movements of hands and arms" (Kendon, 1972, p. 205) and recognized that gesture like speech was organized in hierarchical units. According to Kendon (1980), these hierarchical units included *gesture phases*, *gesture phrases*, and *gesture units*. Gesture phrases (the entire gesture movement from beginning to end) are composed of gesture phases, which include *preparation* (movement to a position for the stroke to start), *stroke* (the part of the gesture that conveys meaning), and *return* (return to rest position), and gesture units are composed of more than one gesture phrase. Kendon's organization with the addition of the gesture phase of *holds* (pre-stroke and post-stroke), that is, holding of the position, by Sotaro Kita and the use of the word *retraction* as well as *return* has become the standard way to refer to the components of a gesture and has enabled researchers to analyze gesture in a consistent way. Of these gesture phases, only the stroke is obligatory within a gesture phrase; the other phases may or may not occur.

McNeill realized "that language and gesture were two sides of one 'thing'" (McNeill, 2005, p. xi) while watching a translator translating his words into French and gesticulating

at a conference in Paris in 1971, and he began systematically researching gesture in the early 1980s. His focus has been on the relationship between language, gesture, and thought, and he used speakers' gestures along with their speech as an enhanced window to observe mental representations and processes (McNeill, 1992).

According to McNeill, speech and gesture express two aspects of thought—the verbal and the imagistic—and develop from a growth point, “the speaker’s minimal idea unit that can develop into a full utterance together with a gesture” (McNeill, 1992, p. 220), a psychological predicate in Vygotskian terms. This growth point consists of both imagistic and verbal aspects. McNeill (2005) proposes an interactive model for verbal thought, an *imagery–language dialect* in which thought, language, and gesture develop over time and influence each other and in which the static and dynamic aspects of language are combined.

As a result of the insights of Kendon and McNeill, speech and gesture have been seen in a new light, and the number of gesture studies has increased. These studies have been conducted by researchers with differing perspectives and have resulted in several different theories being proposed to account for the relationship of speech and gesture (e.g., the work of Hadar & Butterworth, Feyereisen, Freedman, Kita & Ozyurek, and de Ruiter).

Gesture in Second Language Acquisition Research

As a result of Kendon’s and McNeill’s work, a growing number of papers and empirical studies over the past 30 years have considered the role of nonverbal communication and gesture in first language (L1) acquisition (for a review, see Gullberg, de Bot, & Volterra, 2008) and second language (L2) and foreign-language teaching and research (for a review, see Stam & McCafferty, 2008). Studies on gesture in L1 acquisition have examined such topics as the co-development of speech and gesture in the L1 including the developmental trajectories for the different types of gestures, children’s use of gesture space, the relationship between nonverbal behavior and intonation, children’s pointing gestures and their meaning, gesture use during early language development, gesture–speech combinations as a transition to two-word utterances, environmental effects on children’s gesture use, and the age that children exhibit L1 thinking for speaking patterns in speech and gesture. In contrast, gesture in L2 acquisition studies, the focus of this entry, has concentrated on such topics as communicative competence and emblems, learners’ gestures, bilingual development, assessment, teachers’ gestures, and gestures as facilitators of L2 comprehension and acquisition. These L2 topics will be discussed in the following sections.

Although it is the norm in the field of L2 acquisition and gesture to cite the researcher related to each finding, the purpose of this entry is to give a broad overview to a lay audience; therefore, that custom has been set aside for the purpose of focusing on findings.

Communicative Competence and Emblems

Recognizing that communicative competence in another language involves more than just linguistic competence, several researchers (e.g., Pennycook, 1985; Wylie, 1985) have advocated for the teaching of emblems and nonverbal behavior, kinesics and proxemics, in the second/foreign-language classroom, while others have proposed that learners be tested for their nonverbal ability (for a review, see Stam & McCafferty, 2008). In addition, differences between native and non-native speakers’ comprehension of emblems have been empirically tested. The studies found significant cultural and age differences in the interpretation of these gestures: native speakers and older children are much better at comprehending them than non-native speakers and younger children.

Learners' Gestures

Learners' gestures have been examined from several perspectives: the rate of gesturing, the type and function of gestures, their relationship to L2 thinking, and as an aid to L2 learners. Several studies have looked at how language fluency affects gesture frequency (e.g., Gullberg, 1998; Stam, 2006) and found that L2 learners produce more gestures when speaking their L2 than their L1 and that the learners' proficiency level has an effect on the number of gestures they produce, for example, intermediate learners produce more gestures than advanced learners. In addition, Elena Nicoladis and colleagues have found that L2 learners used more deictic gestures per word in their L2 than their L1 and that there was evidence of bidirectional transfer, L1 to L2 (French to English) and L2 to L1 (Spanish to English), in gesture rate between high and low frequency gesture languages.

Furthermore, Gullberg (1998) has shown that learners use gestures as communication strategies to overcome expressive problems such as lexical shortcomings, grammatical difficulties, and fluency-related problems. Stam (in press) has demonstrated that the types of gestures learners use during lexical retrieval vary depending on whether they are trying to retrieve a word or they are eliciting the word from an interlocutor, and Tabensky (2008) has found that the task has an effect on the types of gestures learners use. The gestures used during expository discourse differ from the ones used during interactive discourse and are related to the type of speech that is used.

A number of studies have looked at the speech and gesture of L2 learners to investigate whether their thinking for speaking about motion changes with L2 acquisition with the assumption that if the learner has acquired the L2 conceptualization then their co-speech gestures should look L2-like (e.g., Stam, 2010). These studies have concentrated on different aspects of the motion event, with some investigating the expression of path, others manner, and still others ground. Some of the studies (e.g., Kellerman & van Hoof, 2003) found no shift in the learners' thinking for speaking patterns whereas others (e.g., Stam, 2006) did. Stam proposed that this shift in the L2 learners' speech and gesture was reflective of their developing interlanguage systems and contained aspects of both their L1 speech and gesture system and the L2 speech and gesture system. In addition, Brown and Gullberg (2008) found that the L1 speech and gesture of L2 learners, even with intermediate proficiency in the L2, were affected by learning a second language and that crosslinguistic transfer is bidirectional.

Several studies (e.g., Gullberg, 2008) have examined learners' speech and gesture with referent marking and found that learners have an overuse of lexical noun phrases in maintained reference compared to L1 speakers and that they often mark maintained referents with anaphoric gestures. Gullberg has suggested that the gestures may be lightening the learners' cognitive load and they "could potentially be regarded as a cognitive, speaker-directed communication strategy for grammar and discourse" (Gullberg, 2008, p. 203).

Within a Vygotskian sociocultural framework, the role of gesture in L2 acquisition has been explored in several different contexts. The role of gesture in other-regulated and self-regulated private speech has been examined (see McCafferty & Stam, 2008), and it has been found that the learners' gestures exhibit a self-regulatory function and help them in gaining control of the task they are engaged in. Additionally, the appropriation of L2 metaphoric gestures has been investigated, and it has been found that L2 learners, especially naturalistic learners acquire L2 metaphoric gestures and internalize their concepts even when they cannot express these concepts verbally.

McCafferty (2008) has argued that *mimesis* (imitation) in terms of gesture is an important aspect of L2 development that has been overlooked in L2 acquisition theories. In addition, he has examined the interactions of a Taiwanese learner of English and a native English speaker and found that gestures were used in the co-construction of meaning to create

zones of proximal development. He found that the same learner used gestures as a mechanism to help him think and organize his discourse and beat gestures as a means to help him parse his L2 into syllables and gain control of the language's prosody.

Conversation analysts such as Junko Mori and David Olsher have studied L2 learners' gestures and they have found that "embodied completions" in conversations, that is, the use of gesture or gaze, pantomime, head movements, and shifts in body positions to complete verbal utterances, contribute to mutual elaboration and intersubjectivity, while gesture-enhanced repeats in repairs have the potential to provide learners with intermodal cognitive input, if they attend to them, and promote language learning.

Bilingual Development

The research by Nicoladis and colleagues (e.g., Nicoladis, Mayberry, & Genesee, 1999) has shown that gesture use is related to language development. They investigated the gesture use and the spoken-language development of five bilingual (English–French) boys and found that their use of iconic and beat gestures was related to their language development (Nicoladis et al., 1999). Their use differed in the two languages and was connected to the number of morphemes in the children's utterances. A subsequent study by Mayberry and Nicoladis (2000) found that gesture frequency increased with increased language development and that a change occurred in the types of gestures produced. There was a shift from points to iconics and beats; however, the proportion of iconics and beats produced was not the same as that of adults.

Assessment

Furthermore, the effect of gesture and other nonverbal communication on oral proficiency assessments has been empirically investigated by several researchers. Nambiar and Goon (1993) found that scores on oral proficiency interviews were significantly higher in a face-to-face condition than an audio-only condition because raters had more information about the learners, while Gullberg (1998) found that oral proficiency was rated significantly higher in a video-condition when gestures could be seen than in an audio-only condition and that narrative skills were also rated higher when gestures could be seen. In addition, other research has found that learners were rated higher if their gestures and nonverbal behavior were closer to the norms of the language culture being evaluated regardless of verbal performance and lower if they were not.

Teachers' Gestures

Teachers' gestures have been explored from a number of perspectives. Some researchers (e.g., the work of Allen, Henzl, Lazaraton, and Moskowitz) have conducted descriptive studies of teaching gestures used in the L2 classroom and demonstrated that an important amount of gestures are produced by language teachers whatever the language taught (Spanish, French, English). Others (e.g., the work of Tellier) have focused on the functions of teaching gestures (management of the class, evaluation, and explanation) and the importance of gestures in attracting and maintaining students' attention. Still others (e.g., the work of Sime, Faraco, & Kida, and Hauge) have looked at the types and form of teachers' gestures and learners' perception and understanding of them and found that students noticed different gestures and attached different meanings to the gestures depending on what was relevant for their own learning and that although teachers' gestures were useful, sometimes they were confusing to students particularly, emblematic gestures. Because of the potential impact teachers' gestures have on learners, the researchers of teachers' gestures have also advocated for teaching gestures to be part of language teacher training.

Gestures as Facilitators of L2 Comprehension and Acquisition

The role gestures and nonverbal behavior play in comprehension has been another area of investigation. For example, calling attention to the important role of kinesic behavior in L1 listening comprehension, Susan Kellerman has pointed out the deficiencies in using audio-only material in the L2 classroom for developing listening comprehension and has contended that listening comprehension material should include kinesic behavior. In addition, research on the role of facial cues and gestures on listening comprehension and discourse comprehension has found that both visual information (facial cues and gestures) and proficiency level have an effect on both listening comprehension and the understanding of discourse, and Tellier has found that the presentation of an English story along with gestures allowed French children who had never studied English to understand the story and expressions within the story.

In addition, whether native speakers altered their gestures in a manner similar to what Ferguson had termed *foreigner talk*, that is, whether they simplified their gestures, when speaking with non-native speakers to facilitate their comprehension was examined in the work of Thomas Adams. He found that native speakers used more mimes, iconics, and deictics with non-native speakers than they did with native speakers; however, they used the same amount of metaphors and emblems in both conditions. This issue of gesturing differently to native and non-native speakers has been further investigated by Tellier and Stam (2010) in regard to future language teachers before and after they undergo teacher training.

The question of how gestures can contribute to memorization of vocabulary has also been explored. Allen (1995) found that learners that were presented with emblematic gestures along with French expressions recalled the expressions better than those who were not, and Tellier (2008) found that when children reproduced a gesture during the course of memorizing a word in their L2, they remembered the word better than when they just saw a picture or an illustrative gesture.

Conclusion

In conclusion, the studies exploring the role of gesture in L2 acquisition are varied and shed light on different aspects of the acquisition process and classroom interaction. However, the field of L2 acquisition and gesture is still in an emergent stage, and there is much more research that needs to be done (see Gullberg, 2010, for a discussion of the methodological issues that need to be addressed). Nevertheless, looking at both speech and gesture in L2 acquisition holds promise for enhancing our understanding of the L2 acquisition process, learners' interlanguage systems, their thinking patterns, their understanding of discourse, memorization processes, and the impact that teachers' gestural behavior has.

Second Language Acquisition of Sign Language

BENCIE WOLL

Introduction

The recognition of sign languages (SLs) as fully grammatical languages has had as a consequence a growing interest in SLs and Deaf culture and a proliferation of SL teaching programs throughout Europe and North America. American Sign Language (ASL) has become one of the most commonly taught languages in North America and is widely accepted in higher education as satisfying foreign/second language requirements. However, in spite of the large number of individuals learning an SL as a second language (L2), there are relatively few studies of SL as an L2 (Mayberry, 2006).

Acquisition of a Signed Language as a Second Language (L2)

Both hearing and deaf adults frequently learn SLs as second languages. These include teachers, interpreters, therapists, researchers working with children, and deaf adults who have grown up with a spoken language as an L1. The small but growing literature has begun to emphasize both similarities and differences between learning spoken languages and SLs as L2s. These studies are beginning to shed light on those features of L2 learning which relate to modality. Like spoken languages, SLs are natural languages. Unlike spoken languages, however, SLs use the visual-manual modalities for their expression and reception: produced with the hands, arms, and face, and perceived through the eyes. This means that research on L2 acquisition must recognize that there are two kinds of L2 acquisition: unimodal—learning an additional language in the same modality as the first language (M1)—and bimodal—learning an additional language in a modality different from the L1 (M2) (Emmorey, Borinstein, Thompson, & Gollan, 2008).

For example, L1 learners of an SL may later learn some other SL as an L2, an example of unimodal bilingualism comparable to acquiring two spoken languages as L1 and L2. This is common where SLs are in close geographical proximity, as is the case for Irish SL (ISL) and British SL (BSL) in Northern Ireland (the two SLs are historically unrelated and are mutually unintelligible). An example of bimodal or cross-modal bilingualism is the L2 SL learning by deaf adults and adolescents who are proficient in a spoken L1, which is often in a read and lipread form. Another type of sequential L2 learning of SLs is found in educational programs that teach SLs such as BSL or ASL to preschool and primary school children as a second language (Daniels, 2003). However, the most common context in which SLs are acquired as L2s is by hearing adults.

One important question is whether the sensory modality of the first and second languages changes what we know about L2 acquisition over the lifespan. Another important question for deaf people is whether and how the age of L1 acquisition (often delayed in this population) affects the ultimate outcome of L2 learning (Mayberry, 1993). Clearly several factors must be considered in any account of L2 acquisition of SLs: sensori-motor modalities, the

2 SECOND LANGUAGE ACQUISITION OF SIGN LANGUAGE

temporal order of the L1 and L2 acquisition, and the ages when the L1 and L2 are acquired. Here the primary focus is on sequential L2 acquisition in hearing adults with a spoken language as an L1. Various features of SL as L2 will be discussed here: (a) learnability; (b) iconicity; (c) phonology and motor skills; (d) the role of the face; (e) grammar; (f) the role of gesture; (g) social issues.

Learnability

Although there are no clear findings as to which aspects of SL are harder to learn, a descriptive study by McKee and McKee (1992) reports both student and teacher intuitions regarding the degree of learning difficulty of several features of ASL. Teachers and students agreed that adapting to the visual-gestural modality, that is, becoming comfortable with using the body, was a major area of difficulty. Both groups also mentioned dexterity and coordination in producing and connecting signs, facial expression and other nonmanual signals, spatial indexing through deixis, eye gaze, and body shift and classifiers. Fingerspelling was also rated as highly problematic. Wilcox and Wilcox (1991) also mention nonmanual grammar features, complex morphology, and the use of classifiers as difficult for learners to comprehend as well as to produce.

Iconicity

Unlike spoken languages, where arbitrariness in the referent–symbol relationship is not only predominant but is seen as an intrinsic design feature of language (Sutton-Spence & Woll, 1999), iconicity—a visually motivated relationship between the referent and the symbol—is pervasive in SLs (Taub, 2001). However, studies of the acquisition of SLs as L1 all indicate that iconicity plays only a limited role in young children’s acquisition of SL vocabulary, and there is contradictory evidence as to the role iconicity may play later in individuals who have acquired an SL as an L1 (Thompson, Vinson, & Vigliocco, 2009). In contrast, the first stage of adult L2 learning of SLs is characterized by a marked reliance on the perceived iconic features of signs. Beginning signers use iconicity as a mnemonic aid to remember new vocabulary items for both sign expression and recognition (Campbell, Martin, & White, 1992; Hoemann & Kreske, 1995) and seek visual motivation for every sign form, whether the sign is visually motivated or not. Unlike infants, adults have experience of interpreting gestural representations and this ability facilitates recall and learnability in iconic signs. In Campbell et al. (1992) hearing adult learners of BSL and sign-naïve subjects were presented with different lists of signs in BSL and then were asked to identify signs from the first list in a second list of signs. Those with some experience of learning BSL performed better than sign-naïve subjects. For both groups, iconic signs were easier to recognize than non-iconic signs, suggesting that access to an iconic representation facilitates recall. Early stage L2 learners may recruit gesture and pantomime to aid memory, a strategy perhaps analogous to early stage spoken language L2 learners using the sound patterns of their native language to help them remember the sound patterns of the L2. However, Ortega and Morgan (2010) have shown that this strategy in L2 learners of BSL may lead to articulatory errors.

Although visual motivation is apparent for a large percentage of signs, all SLs have phonological structure—that is—meaningless articulatory units which combine to make the words/signs of the language. Signers process the phonological structure of SLs during language comprehension and production (MacSweeney, Waters, Brammer, Woll, & Goswami, 2008), just as users of a spoken language do.

Phonology

Unlike children acquiring an SL as an L1, hearing adults acquiring an SL as an L2 can perform complex movements with arms and hands and have a fully developed perceptual system. They should thus have no difficulties in perceiving the phonological parameters that constitute a sign. Nevertheless, L2 learners have to develop new motor skills and adjust their attention to capture all relevant features of signs and there is evidence suggesting that hearing adults experience some of the same motor difficulties as children when they acquire a visual-spatial language.

Mirus, Rathmann, and Meier (2001) have shown that under some circumstances, hearing adult learners of an SL tend to proximalize movement just as children acquiring an SL L1 do. They asked four groups to view and repeat signs from an unfamiliar SL. Group 1 comprised deaf native users of German Sign Language (DGS); Group 2 comprised hearing adults with minimal exposure to DGS. These two groups were presented with signs from ASL. The third and fourth groups comprised deaf native signers of ASL and hearing adults with practically no exposure to any SL respectively, who were presented with signs from DGS. Proximalization (transfer of movement from a joint more distant from the body to a joint closer to the body: for example, substituting elbow movement for wrist movement) occurred frequently in all groups, with Group 4, who had no experience of any SL, most likely to proximalize movement. The deaf groups were better than either of the two hearing groups. The authors attribute this to their greater experience of using their bodies as language articulators (i.e., indicating a modality effect). These findings suggest that despite having mature motor systems, those for whom an SL is not just an L2 but an M2 only gradually become sensitive to movement features and how to achieve accurate articulation.

Rosen (2004) examined production errors in ASL lexical phonology made by beginning L2 adult learners. The errors were shaped by perception of sign formulation and poor motor dexterity. Production errors resulting from poor motor dexterity included substitutions, displacements, switches, additions, and deletions. Production errors shaped by perception include mirroring of hand movements, and addition and deletion of features within segments. Rosen explores the applicability of a number of analytical models such as L1 transfer to his data but reports that none capture the essence of phonology production errors in L2 ASL, and proposes a cognitive phonology model to account for the errors.

Face

McIntire and Reilly (1988) examined whether the communicative facial expressions of people who use a spoken language are transferred into ASL facial grammar. They conclude that while preexisting affective facial expression does serve as a transition in acquiring nonmanual grammar in ASL, the learner must first go through a reanalysis stage in which previous knowledge is processed as being linguistically meaningful. This reanalysis process seems to be necessary both for adult L2 learners and for infant L1 learners. This reanalysis also appears to play a role in the L2 acquisition of grammar in SL.

Grammar

Beyond vocabulary learning, L2 learners of SLs must also master morphology and syntax. One problem for L2 learners is that the syntax and morphology of SLs are not always taught. Many courses primarily teach the established lexicon of SLs, along with fingerspelling. This inadvertently encourages beginning L2 learners to express SL vocabulary using the word order patterns of their spoken L1. The result is a kind of learners' signing, where

4 SECOND LANGUAGE ACQUISITION OF SIGN LANGUAGE

L2 content words (vocabulary for people, actions, internal states, and objects) are signed according to the word order of the L1 without the morphology and syntax of the target language.

Spatial Grammar

Taub, Galvan, Piñar and Mather (2008) examined the L2 acquisition longitudinally of three components of ASL: classifier structures, role shift or constructed action structures, and the use of location in the signing space. They tracked the early development of certain spatial skills that are central in the production of these three structures to address whether preexisting spatio-visual skills transfer into the acquisition of the spatial aspects of ASL.

Role shift (the use of changes in body orientation to represent different roles in discourse) was produced with some linguistic nuance early (i.e., correct body part movement and matching facial expression.) However, correct eye gaze for role shift developed more slowly in ASL than facial expression. Ability to use third-person reference in discourse also developed early, with various skills in handling location in signing space patterning together at an early stage.

Taub et al. (2008) see the source of these early skills as the outcome of transfer from preexisting gestural skills. Linguistic transfer—the role of previous linguistic knowledge—is an important topic in the study of L2 acquisition.

Gesture

Although cospeech gesture does not have a grammatical function, it interacts with the grammatical elements of spoken languages in systematic ways (Kendon, 1986; McNeill, 1992). Since gesture makes use of the visual-spatial domain, existing gestural abilities may transfer into the L2 acquisition of the spatial features of SLs. For SLs, these actions are tightly constrained to unify with lexical and grammatical elements, and are used with consistent meanings within an SL community. In contrast, cospeech gestures are loosely integrated with speech, have considerable variation in shape, size and clarity, and vary in what they communicate.

Taub et al. (2008) report a degree of relationship between the ability to establish consistent spatial coordinates in gesture and the ability to establish spatial reference in ASL, and between the ability to use classifier-like handshapes in gesture and the development of verbs of location and movement in ASL. Their research suggests that transfer can occur even when the L1 and L2 are in different modalities. While linguistic spatial skills have no parallel in the spoken modality, preexisting visual-spatial skills may predict the development of spatial skills in an SL. Additionally, gesture as a component of transfer may predict aptitude in L2 SL acquisition, and may also contribute to the creation of teaching strategies and methodologies to make use of learners' preexisting visual-spatial skills.

Social Issues

Pivac (2009) investigated students who had acquired New Zealand Sign Language (NZSL) as a second language (L2) as part of their studies for a diploma in sign language interpreting. The study explored NZSL learning outside the classroom setting through semi-structured interviews in a bilingual context (NZSL and English) to uncover informal learning opportunities especially within the social context of the Deaf community, and individual learner strategies utilized by “good learners” of NZSL. The findings indicated that the social

relationships and networks developed with L1 users, which facilitated access to an array of NZSL learning opportunities, were of key importance. Learner involvement with deaf social networks resulted in significantly improved linguistic, pragmatic, and sociocultural competency. The findings show the importance of research on adult L2 SL learning outside the classroom context.

Conclusions

Research on L2 acquisition of SLs provides a new perspective on L2 acquisition which is not available if only the learning of a second spoken language is considered. In particular, issues of transfer and modality are highlighted by research in this field. These in turn have implications for models of L2 acquisition in terms both of linguistic theory and cognition.

Second Language Acquisition via Second Life

JAMES MILTON

Virtual environments such as Second Life offer learners of foreign languages the possibility of extensive language use which has previously only been possible by visits to a foreign country. These sites are widely patronized by non-native speakers but the language gains which occur, if any, are unknown. This entry therefore pays particular attention to a recent project whose objective is to test the language gains which emerge from dedicated language learning environments in Second Life. These suggest that, if appropriately used, virtual environments like Second Life can be a very valuable asset in foreign-language learning (<http://secondlife.com/>).

Background and Traditional Classroom-Based Teaching

It is an axiom of learning a foreign language that the optimal way to do this is to spend time living and working in the country where the language is spoken. Total immersion in a foreign country allows, in principle at least, maximum exposure to the foreign language, and creates every opportunity for communicative use of the language as learners go about their daily tasks. However, for the majority of foreign-language learners, young children learning at school, this is not an option. As Häcker (2008) notes, exposure to the foreign language is limited to the textbook and the foreign-language classroom for most learners. For motivated learners, particularly of English, there is also access to films, pop songs, and much of the Internet to supplement foreign-language input. For a lucky few, this exposure may be supplemented by a study visit abroad or an exchange program.

If life in a foreign country provides almost limitless time and exposure to the rich variety of the foreign language, the learning environment of the classroom is very different. The time available is often strictly limited by the demands of other subjects in the curriculum but, as Milton and Meara (1998) note, the time available for learning a foreign language is crucial to success. Studies show how limiting the nature of the textbook and the classroom can be. Häcker (2008) notes how few structures and vocabulary are taught in UK foreign-language classrooms, for example. Tschichold (2008) points to the emphasis on only the most frequent vocabulary in these textbooks. Perhaps explaining both these observations, Milton (2009) points to the absence of thematic variety and the high degree of repetition involved in the foreign-language textbooks used in the United Kingdom. A study by Richards, Malvern, and Graham (2008) observes how dependent French foreign-language exam grades in UK schools are on knowledge of the most frequent 1000 words only. It seems that textbooks and current educational systems can provide very limited exposure to the foreign language resulting in insufficient knowledge for effective communication.

The language classroom can also be a poor place for language interaction between learners. Even in the best regulated of classrooms there will be a tendency for the teacher, who knows the subject, to talk and for the pupils, who do not, to listen. Good language teachers attempt to modify this and give every possible opportunity for learners to talk

but in a classroom with 20, 30 or even 40 students, the amount of language they can produce must be small. In a study of a single oral class by Al-Saif (2011) it is clear that teacher talk outweighs the contribution of all learners combined, more than double, that the learners produce only a handful of words each, and that the language environment appears to be lexically poor.

The Opportunity for Second Life and Interactive Virtual Environments

One of the benefits offered by technology assisted language learning and teaching is that, unlike the traditional classroom, it can offer much greater opportunity for language use and interaction, and because of the nature of the Internet, interaction with native speakers. Wikis and blogs, for example, encourage learners in language production. They can also encourage interaction, as users collaborate in the production of texts or engage in discussions about them. Sykes, Oskoz, and Thorne (2008, p. 530) note that this is a change in the learners' usual stance from consumers of knowledge to full participation in the educational community. This enhances learners' reading and writing in the foreign language (Ducate & Lomicka, 2005) and students perceive benefits, particularly in intercultural competence, through linking this way with native speakers (Elola & Oskoz, 2008). The opportunity for developing communicative competence and pragmatic awareness, producing language which is appropriate to the situation in addition to being meaningful, is thought to be particularly important (Sykes et al., 2008, p. 535). There are also potential limitations with wikis and blogs since exchange of information through these media, are generally written and asynchronic. There can be a considerable time delay between each exchange. This may help the learner struggling to assemble text for communication quickly but one of the challenges for foreign-language learning is to develop the speed and automaticity of response which is necessary for fluent oral communication.

Virtual environments in particular offer the opportunity for real-time oral interaction in a variety of relatively normal-looking settings, using the learner's foreign language. It should not be a surprise, therefore, if virtual travel in a 3-D virtual environment arouses the interest of teachers and learners alike. Most children will be aware of the possibilities of 3-D worlds through computer games. In these games the world is usually quite narrowly confined and the users move their characters, or avatars, around this world to solve puzzles or battle aliens. But other 3-D worlds are broader in scope, run online, and offer adults the opportunity to travel around the virtual environment meeting other avatars and talking with them in real time. There are virtual shops to visit and clothes and other items can be bought using virtual money. There are virtual bars and nightclubs where your avatar can dance. Such a site can offer a more broadly social function and, reflecting the real world, can have different country or city locations. In one such virtual world, Second Life for example, there is a virtual London, a virtual Dublin, and a virtual Athens where you can take a walk around a virtual acropolis, just to pick three sites at random. As an example of what this looks like, Figure 1 shows a screenshot of this author's avatar in virtual Trinity College Dublin.

The Theoretical Underpinning of Second Life and Interactive Virtual Environments

For learning to occur, these environments must present language and provide the opportunity for learners to use it. Where there is no language there will be no learning. The presentation of the foreign language and the way learners engage with it is also crucial

Figure 1 Screenshot of an avatar appearance in the Second Life® virtual learning environment (Second Life is a trademark of Linden Research, Inc.)

for success. Clark and Gruba (2010) report on an attempt to learn Korean using a social networking site where the materials were inappropriate, dull, and routine. The outcome was poor motivation and less than optimal learning.

The interaction which is part of membership of virtual environments offers features which are thought to be a particular benefit to language learning. The opportunity for the use of authentic language in meaningful tasks, if these can be created in the virtual environment, fits well with the tenets of task-based language learning: an approach which is designed to foster fluency and learner confidence (for example Brumfit, 1984; Willis, 1996; Willis & Willis, 2007). This approach also fits with social interactionist theory and competition theory (MacWhinney & Bates, 1989) where extensive language exposure is a requirement of learning: virtual environments are thought to offer the opportunity for lots of exposure. It should further provide the learner with comprehensible input gained through interaction. Negotiating meaning and modifying output, the processes learners engage in to get a clear understanding of each other, are considered central to second language acquisition (Long, 1985, 1996).

If the opportunities for foreign-language exposure and interaction can be harnessed then there also appear to be real opportunities for language gain.

Practical Suggestions for Second Language Learning in Virtual Environments

There is the opportunity for real-time communication in a site such as Second Life but the nature of the environment also has limitations for pedagogy. Much of the interaction of these environments can be language free. Young learners particularly like the experience

of flying in Second Life, for example, but this requires no language at all. Users also like changing the appearance of their avatar but this also involves little or no language. To be effective, use of the environment must lead learners in directions that will offer the opportunity for improvement.

The European-funded lifelong learning project entitled Vill@ge (Virtual Language Learning through Edutainment Activities; 143370-2008-LLP-GR-KA2-KA2MP) uses Second Life as a platform and is an example of how the creators of language learning environments have attempted to harness the benefits of these environments for learning, and avoid the pitfalls of nonlinguistic interaction (<http://village.exodus.gr/echome.asp?lang=2>). The Vill@ge island therefore has a number of virtual buildings designed to fit with the aims the learners are set. University level learners who are studying English for business and commerce are provided with virtual banks, travel and estate agency shops, and show homes to visit and practice in. Primary level learners have virtual supermarkets, a clothes shop, a zoo, and a karaoke bar to visit. The names of animals, clothing and food and drink, and structures associated with these are standards of elementary language courses.

When visiting these locations, learners are paired with a native speaker in another country and they are set tasks or role plays to carry out. The university learners may, for example, take the role of a bank assistant and have to deal with native-speaking customer avatars who, within the role play, are trying to open an account or take out money. Primary age learners are set tasks such as shopping. One avatar has a shopping list and has to explain to the other avatar what needs to be bought and put in the virtual trolley. Figure 2 illustrates the shopping environment in the supermarket. If an object is not known then it can be found and pointed at by way of explanation, or the users can explain, illustrate, and negotiate meaning. Users have the option of speech or typing in which to communicate and learners in particular appreciate the opportunity to see the language written down as an aid to learning. Crucial to the success of these activities is the way language use is a requirement of interaction, so if you want to change the clothes on your avatar for example, you have to negotiate with another avatar to do this. If your language lets you down, you cannot achieve what you want. Other features of the virtual world, like

Figure 2 Screenshot of the supermarket shopping task on the Vill@ge island using the Second Life® virtual world

Figure 3 Screenshot of the Pictionary language support feature on the Vill@ge island virtual world program

flying or the use of cars, can be held back as rewards for the successful completion of language tasks.

Primary age learners will typically be low level and will require language support features to be built into the environment. Learners have access to a dictionary, or perhaps more accurately a pictionary, via virtual computers in the program and where unknown words can be found and heard. Figure 3 gives a screenshot of this facility on the Vill@ge island and which, for the purposes of this European program, works in English, Greek, and Hungarian.

The environment can also be changed and obstacles added for games where learners have to direct each other through the maze of buildings. Crucially, the dedicated island allows learners of this age to move uninhibited through the environment and to interact with every avatar. Access to the island can be controlled and restricted, and there is no opportunity in this environment for unadvertitious meetings with unknown and potentially predatory adults.

An interesting potential feature of this environment is the use of bots as customers, taking advantage of the predictability and formulaicness of language in some situations. These bots, avatars driven by the computer rather than by another person, can potentially be preprogrammed with questions, and to listen out for keywords in the answers they receive which can trigger relevant follow-up questions. This is a formidable programming and linguistic task, of course, but it offers a pointer to the future of these programs.

Details of Second Life and access to the virtual world it provides can be found at <http://secondlife.com/>. Details of projects which make use of Second Life explicitly for virtual travel and foreign-language learning can be found at <http://village.exodus.gr/> and <http://www.britishcouncil.org/hongkong-english-secondlife.htm>

The Evidence We Have for Learning in Virtual Environments

The subject of technologically assisted language pedagogy is a vibrant area of research (Thorne & Reinhard, 2008) but, as Clark and Gruba (2010) comment, comparatively little of this work is directed at social networking sites and virtual environments. Indeed, Chapelle (2010, p. 72) stresses the absence even of good methodologies for assessing the benefits which might emerge from use. From the information we have it seems that research supports the idea that high levels of interaction and the negotiation of meaning result from using these virtual environments (for example, Shih & Yang, 2008, and Sadler and Nurmukhamedov reported in Thorne, Black, & Sykes, 2009, p. 809). This may be the product of the way working through avatars reduces communicative inhibition and encourages risk taking in language use (Peterson, 2010). There appear also to be benefits in terms of motivation and the learners' attitude to learning and correction (Kuriscak & Luke, 2009). Milton, Patrikakos, Antonopoulou, Papakostopoulou, & Papatheodorou (2000) and Filipoupolitis (2005) report increases in both length of utterance and in the speed with which these utterances were produced, suggesting increases in fluency, through communication in a virtual environment. However, despite the considerable potential, as Sykes et al. (2008, p. 535) note, there is little research addressing the effectiveness of the use of these environments. The question, *Do learners really get better in these environments?* remains unanswered.

Data collected from use of the Vill@ge environment (Milton, Szabo, Orosz, Griffiths, & Bonabos, 2011) confirms the high volumes of learner language, mostly oral, which are produced. In Al-Saif's (2011) study, learners in a traditional oral class produced fewer than twenty words each on average in a 45-minute class. In the same time, primary learners performing tasks in Second Life produced on average over a hundred words each, and university level learners over seven hundred. A feature of the younger learners' language use is the comparatively limited speed with which language interaction can take place. Oral interaction can produce unmanageable demands in terms of the speed with which low level learners can process language, and the speed with which they can respond. A more workable use of the environment, for these learners, appears to involve the use of typed messages in support of speech (also noted in Milton & Garbi, 2000). The interaction does not appear as stilted as would be the case if this were purely spoken language. Among university level learners, the use of typed messages is much more restricted. They spell out unknown vocabulary and use text-messaging conventions, such as ;-), to provide encouragement and support for each other.

University level learners in this study also demonstrated increases in the quantity of language produced, and length of utterance, with each successive session in Second Life. This suggests that the learners become more fluent through interaction in this environment: more confident in using their English productively and quicker in recalling the language they want. Where these learners were taught Hungarian by their partners for an hour, the rate of vocabulary uptake appeared high: about forty words were learned receptively on average. This is comparable with the vocabulary focused informal activities described in Horst and Meara (1999), Milton (2008) and the bilingual list learning experiment in Fitzpatrick, Al-Qarni, and Meara (2008).

Limitations of Second Life

If these findings appear encouraging there are also shortcomings and limitations to the business of learning, and organizing language learning, through these environments. A principal one is the transience and cost of much of the technology that makes sites such

as these possible. Sites such as Second Life require computers with fast processing and high specification graphics cards in order for them to run successfully. Such machines can rapidly become outdated and the cost of keeping updated is far from small. Allied with this problem is the way technology develops so that the sites themselves become outdated and are superseded by others. If dedicated facilities and materials have been created for a site which then becomes redundant, then the time and effort used to create the learning environment will also be redundant. Dedicated materials and sites may be necessary because of the issue of security on sites which may not be monitored where young learners are interacting with others whose purpose for being there may be a long way from language learning. Anyone, in principle, can use a site such as Second Life and begin to use a foreign language but for most young learners access may have to be limited and controlled to ensure they are not placed in the way of danger. This type of security comes at a cost. The use of these sites may not be a cheap route to language learning after all.

A second shortcoming lies in the nature of the environment itself which, while fast and realistic compared to the sites available even a few years ago, still fails to mimic completely the nature of interaction in the real world. The use of avatars means that features of interaction which govern language, gestures and facial information such as lip shape, are missing. Necessary elements of language such as turn taking, and even comprehension itself, are hindered by their absence. There are gestures available in these sites, shrugs and winks for example, but these are limited and are hard to manipulate with the facility that would be the case in real life. Other aspects of the environment are also limited. Handling items on supermarket shelves, or placing posters on walls, either cannot be done or requires extensive and expensive programming dedicated to a learning activity. The interaction may be fun, and that will encourage the use of these sites and so foster language use and learning, but these sites are not yet a complete imitation of a real visit to a real foreign country.

Second Language Experimental Pragmatics

NAOKO TAGUCHI

Experimental study is a type of quantitative research developed in the natural sciences to establish a cause–effect relationship between variables in a tightly controlled study design (Dörnyei, 2007). In the field of interlanguage pragmatics, the causal links have been explored by such questions as: “What effects does something have on pragmatic development?” and “What is the reason for the variations observed in learning outcomes?” Causal factors examined in previous research include learner-specific issues such as age, gender, and motivation; external factors such as types of learning context and length of residence in the target culture; and classroom factors related to instructional methods and practice. This entry will discuss those factors in two categories: learning context and instructional intervention. Under each category, example experimental studies will be presented in light of their methodologies and the types of cause–effect relationships that they tried to establish.

The Effect of Learning Context in Pragmatic Development

The causality links between learning context and pragmatic gains have been explored by a line of studies that directly compared a second language (SL) context (learning a language in a country where the language is spoken) and a foreign language (FL) context (learning a language in a country where the language is not spoken) for their effects on pragmatic gains by sampling learners from each physical environment. These studies typically recruited a group of learners in a study-abroad context and measured the learners’ pragmatic progress over time. The researchers then compared the results of the first study with data obtained from a domestic, at-home group. The underlying premise is that the SL context is a likely causal variable for pragmatic development because of abundant opportunities for pragmatic practice. Learners have opportunities to observe how people convey appropriate levels of politeness and formality in speech acts or how people express meaning in an indirect manner. These opportunities available in the host country are considered to facilitate pragmatic development.

Taguchi’s (2008) study is one example in the line of study-abroad research. She compared SL and FL learners of English for their ability to comprehend implied speakers’ meaning (see example test item below). Here, the target implied meaning is in Susan’s second utterance, and the correct inference is that Susan does not like the job.

- Dave: Hey Susan. I didn’t know that you’re working here.
Susan: Yeah, I’m working in the Student Union cafeteria. I work there Monday through Friday, starting at six.
Dave: You sound busy. Do you like the job?
Susan: My mother wanted me to take it.
Question: Does Susan like the job?

2 SECOND LANGUAGE EXPERIMENTAL PRAGMATICS

The computerized listening test had 60 such items, including 48 targets and 12 filler items. Participants were Japanese students of English in the USA (ESL) and in Japan (EFL). They were equated in terms of age, previous learning experiences, and initial proficiency. The listening test was administered twice to the groups over time to see the gains in accuracy and comprehension speed (i.e., response time or average number of seconds taken to answer each item correctly). Results showed that both groups made significant gains over time. However, participants from the EFL group gained far less in speed than in accuracy. In contrast, ESL learners showed significant improvement in comprehension speed with a sizable effect size, but with only marginal improvement in accuracy.

The causality claims drawn from these studies are mixed. While the majority of the findings reveal an advantage of SL over FL context in pragmatic performance, evidence also exists suggesting that FL learners demonstrate better performance than SL learners. Furthermore, as shown in Taguchi's study, the positive effect of residence abroad was not all-encompassing over different pragmatic aspects; some pragmatic targets were better assisted by the experience of living in the SL context, while others were susceptible to learning context.

For example, Bardovi-Harlig and Dörnyei (1998) documented the superiority of SL learners over FL learners in their ability to detect pragmatic and grammatical errors in speech acts of request, apology, suggestion, and refusal. Learners watched video scenes in which the interlocutors' speech acts contained either grammatical or pragmatic errors. One example was as follows:

Context: It's Anna's day to give her talk in class, but she's not ready.

Teacher: Thank you, Peter, that was very interesting. Anna, it's your turn to give your talk.

Anna: I can't do it today but I'll do it next week.

Was the last part appropriate/correct? Yes No

If there was a problem, how bad do you think it was?

Not bad at all ____ : ____ : ____ : ____ : ____ Very bad

Participants were learners of English in Hungary (EFL) and the USA (ESL). EFL learners detected more grammatical errors than ESL learners did, while ESL learners detected more pragmatic errors. The findings were confirmed by Schauer's (2006) replication study which found that, compared with EFL learners in Germany, German ESL learners in England recognized a considerably higher number of pragmatic errors.

However, Niezgoda and Röver's (2001) study, another replication of Bardovi-Harlig and Dörnyei, yielded contrasting findings. EFL learners in the Czech Republic detected a higher number of pragmatic and grammatical errors in speech acts and judged both error types as more serious than ESL learners did. EFL learners' sensitivity to pragmatic inappropriateness was attributed to the fact that they were advanced speakers enrolled in a teacher-education program. Proficiency also interacted with the appropriateness judgment. Low-proficiency learners in both environments recognized more pragmatic than grammatical errors and rated pragmatic errors as more severe, but the tendency was the opposite for the high-proficiency learners.

In summary, the cause-effect relationships between learning context and pragmatic development have yielded a mixed picture. Some studies supported the facilitative effect of SL over FL context, but others did not. The residence-abroad experience also brought about different effects according to pragmatic targets. For example, Röver (2005) showed that the decisive variable for the comprehension of routines was study abroad, while proficiency played a crucial role in the comprehension of implied meaning and production of speech acts.

These mixed findings also suggest challenges of experimental studies with learning context as a variable. One difficulty in research design relates to “selection bias,” meaning that the outcome differences are artifacts of the differences in preexisting characteristics of the groups (Larzelere, Kuhn, & Johnson, 2004). This is a likely problem here because participation in the study-abroad program is voluntary, and thus those who choose to locate themselves in a SL context might be more motivated than those who remain in a FL context. Without groups being comparable, it is difficult to eliminate competing explanations for the observed differences. A larger problem relates to the definition of learning context. Many factors operate simultaneously in one context, and it is very likely that the multiple variables interact with individual learners’ characteristics such as motivation, attitudes, and proficiency to yield sizable gains. Hence, it is virtually impossible to control all the factors involved in a learning environment and attempting to do so might result in an artificial laboratory setting that does not present a realistic, intricate picture of the context.

The Effect of Instruction in Pragmatic Development

Instructed learning that focuses on pragmatics is a growing area of research, as shown in the mounting experimental studies published since the beginning of the 21st century and a few edited volumes that focus on instructed pragmatic acquisition (Rose & Kasper, 2001; Alcón & Martínez-Flor, 2005). These intervention studies have examined whether and how teaching affects the acquisition of pragmatic knowledge by comparing different instructional methods for their relative effects. These studies typically use a “pretest/posttest control-group design” in which treatment groups who received different instruction are compared pre- and post-instruction, and then compared to a control group who received no instruction. Any differences in the results among groups are attributed to the only difference between them—the treatment variable.

One popular label used to categorize instructional methods and compare their effects is explicit versus implicit instruction. The former involves a direct explanation of the target pragmatic features followed by focused practice, while the latter withholds explanation but provides ample input and practice opportunities in which learners develop implicit understanding of the target pragmatic forms and their uses.

Takahashi (2001), for example, compared four instructional conditions in teaching English request-making forms (e.g., “I was wondering if you could VP”; “Do you think you could VP?”). The four conditions included: (a) “explicit teaching,” in which students received explanation about proper request forms in a situation; (b) “form comparison,” in which students compared their request forms with those of native speakers; (c) “form search,” in which students identified target request forms in dialogues; and (d) “meaning focused,” in which students listened to dialogues that contained request forms. The treatment sessions were conducted over four periods, each lasting 90 minutes. Instructional effect was measured by a discourse-completion test (DCT) in which participants wrote down request forms in response to situational scenarios. Results revealed that the explicit group outperformed all other groups in producing correct request forms.

In contrast, several studies showed that implicit instruction is equally effective in pragmatic development. For example, Martínez-Flor and Fukuya’s (2005) study compared explicit and implicit instruction in the acquisition of a speech act of suggestion in L2 English. The explicit group received direct explanation about suggestion expressions after watching video clips. The implicit group did not receive explanation but watched video clips in which target suggestions were highlighted in boldface. Learning outcomes were measured by a written and oral DCT. No significant differences were found between the two groups posttest in the appropriateness of the suggestion expressions. The findings imply that, as

long as the target forms are made salient during intervention, implicit methods could produce similar effects to explicit instruction.

In addition to the explicit–implicit dichotomy, the deductive–inductive opposition has also been examined in relation to instructional conditions in experimental studies. A deductive approach involves explicit explanation of rules followed by their applications, while an inductive approach involves discoveries of rules through exposure to examples (Decoo, 1996). Takimoto (2008) applied these approaches to the teaching of requests in L2 English. Participants were divided into four groups: a deductive group, two inductive groups, and a control group. The deductive group received explanation about request forms and completed the “structured input tasks” in which they read a conversation involving a request-making situation and selected the appropriate request form from two alternatives. One inductive group completed the “structured input tasks” too, but did not receive explanation. Another inductive group completed problem-solving tasks in which they compared request forms in dialogues. Results showed that the three treatment groups outperformed the control group. There was no difference among the treatment groups, except that in the listening test the deductive group could not retain their learning at delayed posttest.

These instructional intervention studies are good examples of experimental studies in interlanguage pragmatics research. These studies observe basic considerations of experimental methodology—the use of a control group, tight control of treatment conditions, and use of pre- and posttests. However, a limitation of many of the studies is that they were not true experimental studies: they were quasi-experimental studies because they used intact groups and did not use random group assignments to create the comparisons from which treatment-caused change is inferred. Several techniques could help minimize pretest differences between the treatment and control groups, such as matching participants from each group on a case-by-case basis on one or more variables or using analysis of covariance, a statistical method that adjusts preexisting differences (Dörnyei, 2007). Yet not all intervention studies in pragmatics have used these techniques.

Despite these limitations, quasi-experimental studies have an advantage in that treatments take place in authentic environments using genuine class groups, consequently enhancing the generalizability and ecological validity of the studies. In addition, some improvements are seen in more recent instructional studies, including the use of multiple assessment measures of learning outcomes and explicit reporting of their reliability (e.g., Takimoto, 2008; Tateyama, 2009), use of a delayed posttest to measure robustness of learning (e.g., Takimoto, 2008), and a relatively large sample (e.g., 130 participants in Pearson’s 2006 study). These features add to the rigor of the experiment and enhance the validity of the claims drawn from the findings. Another notable trend is the use of computer technology to implement instruction (e.g., Kakegawa, 2009; Sykes, 2009; Utashiro & Kawai, 2009; Li, 2011). Use of computers in instructional studies could help enhance the quality of experiments by ensuring the comparability of the amount and format of instruction between control and treatment groups.

One issue that merits attention in instructional studies is the choice of measures used to assess learning outcomes, and the degree of correspondence between the treatment and the assessment measures. While studies usually provide an explicit rationale for their selection of particular instructional methods, very few studies state their rationale for the choice of outcome measures. Choosing the right outcome measures is critical because the types of measures often function as moderating factors for observed learning benefits. Hence, when designing an experiment, it is important to clarify what skills and knowledge components the instruction intends to target and whether post-instruction measures could adequately assess the areas targeted in instruction. For example, in Martínez-Flor and Fukuya’s (2005) study, the instructional target was the syntactic forms of suggestion expressions, and learning was measured with a DCT and role-play tasks in which participants produced the speech act of suggestion. The speech act was evaluated by native-speaker

raters, but the study did not report the precise evaluation criteria used by the raters or what aspects of speech act the raters focused on. It is possible that the raters were focusing on other aspects of the speech act (e.g., openings and closings, affective strategies) than the suggestion of head acts (the minimal linguistic unit used to realize the speech act) targeted by the instruction. Furthermore, very few studies have reported who the raters were or what went on during the norming sessions. Because the types of outcome measures inevitably affect findings, careful selection and thorough description of them are essential in experimental studies.

Conclusion

In summary, experimental studies in interlanguage pragmatics have utilized a variety of techniques to examine the effect of one variable on the other in a format of controlled laboratory experiments. These studies have made great effort to control extraneous, intervening variables. In studies that examined the effect of learning context in pragmatic development, researchers have tried to create groups that are comparable in age, background, and proficiency but differ in the context of study. On the other hand, in instructional studies that examine the effect of specific teaching methods on pragmatics learning, effort has been made to control various aspects of treatment conditions such as length, timing, and delivery of instruction. Recent developments in technology hold great promise in introducing consistency in treatment, thereby enhancing comparability among experimental conditions. Future experimental pragmatics will continue to expand its scope by adding more variables to examine and enhancing the quality of experiments.

Second Language Pragmatic Development

MIDORI ISHIDA

Research on the development of second language (L2) pragmatic competence began as early as the late 1970s and became a systematic area of inquiry within interlanguage pragmatics research from the mid-1990s. As a response to the calls for developmental studies of interlanguage pragmatics by Kasper and Schmidt (1996) and Bardovi-Harlig (1999), quite a few studies have been conducted to investigate the route of development, roles of routine formulas, the relationship between grammatical and pragmatic development, and factors that affect pragmatic development. While early studies of interlanguage pragmatics in the tradition of cross-cultural pragmatics focused on speech acts such as requests, apologies, complaints, suggestions, refusals, compliments, and responses to them, developmental studies of L2 pragmatic competence have considerably expanded its focal objects of learning. Such studies cover not only a range of speech acts but also other social actions such as greetings, conversation openings and closings, and agreeing and disagreeing. The use of particular linguistic resources such as discourse markers (e.g., *but*, *y'know*), modal expressions (e.g., *I think*, *might*), and forms indicating politeness and other social meanings including stances and social relationships (e.g., French address forms *tu* and *vous*) are also the focuses of developmental L2 pragmatics studies. Moreover, new studies of L2 pragmatic development examining interactional competence, with which L2 speakers contribute to the collaborative accomplishment of a social activity within an ongoing social encounter (e.g., closing a conversation, making a collaborative decision), are starting to surface.

Major Findings of Developmental Changes

Research on L2 pragmatic development has shown certain routes of development over time. The longer the period of L2 learning and the higher the general proficiency, the more aware of pragmatic errors L2 speakers become. However, development of perceptive abilities does not guarantee the development of productive abilities. Developing sensitivity for situational constellations, or sociopragmatic competence, seems to lag behind development of pragmlinguistic features (i.e., deployment of linguistic resources for making particular pragmatic actions), especially in a foreign-language context, where the target language is not used as the primary medium of social interaction. However, L2 speakers gradually decrease inappropriate performances that are based on their first language (L1) and their performances approximate more to those of L1 speakers of the target language (TL; e.g., Barron, 2003), although they do not become equivalent. On L2 speakers' performance of face-threatening acts such as requests and apologies, the head acts (i.e., the core of the speech acts) are at first direct with reliance on illocutionary force indicating devices (IFID; e.g., *I'm sorry* for apologies; *Can you?* for requests), but become more indirect by means of syntactic and lexical downgraders. In addition to more refined use of internal modifications, L2 speakers also expand the range of external modifications that support the head act.

Specifically on the development of competence in performing requests, extensive research has revealed a rather consistent route of development, through both cross-sectional studies

and longitudinal case studies (e.g., Ellis, 1992; Achiba, 2003): At the most rudimentary stage of development, L2 speakers with little grammatical knowledge heavily depend on the context, for example, by simply naming the object that they are requesting to obtain and using no verb in the head act. Their requests are direct with no mitigation at first (e.g., *Come here*), but gradually become indirect. Formulas such as *please* and *Can I?* play a vital role in specifying an action as a request, and later use of conventionally indirect strategies such as *Would you mind xx-ing?* allows L2 speakers to fine-tune their requests. With higher proficiency, L2 speakers' requests become more TL-like: They use a wider variety and a greater number of internal modifications for downgrading (e.g., *I was wondering if you could possibly xx?*) and external modifications for providing support for the request. With a greater repertoire of linguistic means, L2 speakers also gain abilities to perform more sociopragmatically appropriate actions according to the context.

With regard to developmental changes in the use of routine formulas, at the earliest stage of development, L2 speakers use formulas (e.g., *Can I get xx?*) to accomplish certain actions despite their limited command of linguistic structures. Overgeneralized use of one formula for a range of functions occasionally results in pragmatic failure. However, over time L2 speakers begin using formulas productively by understanding their grammatical constituents (e.g., *Can S V?*) and with more sophisticated command of linguistic structures. The functions that a formula serves also change, for example, from using *please* simply as a marker of requests to using it as a marker of politeness for modifying a request (Achiba, 2003; Barron, 2003). L2 speakers also refine the use of formulas within the sociopragmatic parameters for its use. TL-like formula use helps reduce verbosity, although proficient L2 speakers may become overly verbose due to their command of linguistic structures (e.g., Blum-Kulka & Olshtain, 1986).

As proficient L2 speakers' non-TL-like verbosity suggests, L2 pragmatic development is not a linear process corresponding to proficiency gains. While some studies found that a high level of grammatical knowledge was necessary for achieving high pragmatic competence (e.g., Barron, 2003), there have also been reports that grammatical knowledge does not guarantee higher pragmatic competence (e.g., Salsbury & Bardovi-Harlig, 2001). Moreover, grammatical competence may not be necessary for performing certain pragmatic actions, as found in Schmidt's (1983) study of an L2 speaker of English, Wes. Despite a rudimentary level of his grammatical competence, Wes was able to perform certain actions (e.g., saying *Sitting?* instead of *Shall we sit down?*) and later his incorrect grammatical construction eventually disappeared. Precedence of pragmatic competence over grammatical competence was also observed in a series of longitudinal studies of modals used by L2 speakers of German at the beginning level (e.g., Dittmar & Terborg, 1991). Kasper and Rose (2002) propose the universal pragmatics principle to explain such findings: Even with a rudimentary level of grammatical competence, L2 speakers can exhibit considerable levels of pragmatic competence when participating in L2 social interactions, due to their already developed L1 pragmatic competence which carries across languages. Yet they still need to learn TL practices in areas where L1 and L2 norms and expectations differ, and linguistic realization of L2-specific practices can be achieved with higher grammatical knowledge of the L2.

Factors Affecting Developmental Processes

Research has found that, in general, L2 speakers rarely attain competence equivalent to that of L1 speakers despite their relative pragmatic development, even with higher general proficiency and a longer period of L2 learning in the TL community. Several cognitive explanations for such limitations have been provided, including the lack of noticing

(Schmidt, 1993) and limited control of processing the L2 (Bialystok, 1993). Schmidt hypothesized that the necessary condition for pragmatic development is the L2 speaker's allocation of selective attention to L2-specific pragmatic practices. Schmidt's noticing hypothesis has motivated researchers to experimentally investigate effects of instruction that assists L2 speakers' noticing of specific L2 pragmatic practices. The experimental research collectively suggests that focused instruction is better than exposure alone, and effective when explicit explanations are given. However, even when higher pragmatic knowledge is achieved through explicit instruction, L2 speakers may not become pragmatically fluent, for example, at responding to L1-speaking interlocutors, as found in House's (1996) study. House explains her finding through Bialystok's proposition that adult L2 speakers' main task for achieving higher pragmatic competence is to attain high control of processing of the L2 in real time.

Other factors affecting pragmatic development include L1–L2 transfer, length of residence in the TL community, and availability of relevant input and corrective feedback. While more positive transfer (resulting in TL-like performance) and less negative transfer (resulting in non-TL-like performance) of L1-based pragmalinguistic and sociopragmatic knowledge are observed in L2 speakers with higher proficiency, transferability is affected by various factors such as the targeted pragmatic actions, proximity of the L1 and the TL practices, and the L2 speaker's perception of the proximity. Furthermore, although there are benefits for L2 speakers living in the TL community, various pieces of research have reported that such an environment does not guarantee pragmatic development. Certain areas of pragmatic competence (e.g., routines of greeting and leave-taking, advice-giving, refusal of offers) develop in a relatively short period of time, but others (e.g., compliments, use of certain modal expressions) take longer. This may be due to varied availability of relevant input and corrective feedback. Ethnographic studies have shown that the relative status of the L2 speakers and the kind of social activities that they engage in have particular constraints on the input and feedback that they receive (e.g., Siegal, 1994). It has also been found that some L2 speakers do not follow TL-like practices even with enough grammatical and pragmalinguistic knowledge and processing control, possibly to intentionally deviate from the perceived TL norm as an act of maintaining their sense of identity (e.g., Siegal, 1994; Barron, 2003). Such findings evoke the question of the adequacy of setting TL speakers' normative performance as the ultimate goal of L2 pragmatic development.

Expansion of Research Approaches

Research on L2 speakers' subjectivity suggests the need to expand the views of language and language learning for the study of developmental pragmatics. One of the relevant theoretical frameworks that developmental L2 pragmatics research has drawn on since the late 1990s is the theory of language socialization (Schieffelin & Ochs, 1986). The theory explains language learning as a process that is interconnected with the process of attaining a competent membership in a social group. L2 language-socialization research has shown that L2 speakers are not automatic processors of L2 input but are agents who choose their own pathways of language learning and use. Through ethnographic studies, researchers have revealed contextual details in which L2 learners' pragmatic development is facilitated or constrained. For instance, age has been revealed as an important contextual factor not so much because of the speakers' cognitive capacity but because it influences the ways in which others interact with the speakers. Siegal (1994), for example, found that L2 speakers of Japanese in their early 20s were regularly spoken to in the informal style during their stay in Japan while such input was infrequent for a middle-aged woman. As Siegal's study illustrates, the context for learning is constrained by the conduct of interlocutors and the community's attitudes toward learners. The ideology of host communities that

high competence is difficult to attain in an L2 is also constricting because L1 speakers with such an ideology may use simplified foreigner talk and employ different standards for L2 speakers. Furthermore, in non-pedagogically oriented interactions, adult L2 speakers rarely receive explicit feedback on their pragmatically deviating actions (e.g., DuFon, 1999).

Based on these findings, we can see the need to examine in detail the exact nature of interactional organizations to deepen our understanding of the mechanisms of learning that lead to L2 pragmatic development. A small but increasing number of recent studies have explored this issue by applying theories and methodologies that are established in other disciplines. For example, using language socialization theory, Ohta (1999) showed that L2 speakers develop competence in providing listener responses through participation in the interactional routine of question-answer-response sequences. Because novices can gradually take more control of the routines through repetitive participation, interactional routines are considered an important site for language socialization. The sociocultural theory of L2 learning (Lantolf, 2000), which sees language-mediated interactions as important tools for expanding L2 speakers' potential, also provides a theoretical framework for understanding L2 pragmatic development. For instance, Belz and Kinginger's (2003) study of telecollaborative communication showed how L1-speaking interlocutors' use of address form and their explicit assistance (e.g., *Use "du" to be more personal*) helped L2 speakers of German develop their competence in using address forms of solidarity. Moreover, recent studies that employ conversation analysis reveal in detail the processes in which higher pragmatic competence emerges even within a short space of time and through instruction (e.g., Huth, 2006; Ishida, 2006; Gonzalez-Lloret, 2008). For example, through microanalysis of decision-making activities that an L2 speaker and an L1 speaker of Japanese engaged in during a 10-minute interactional task, Ishida (2006) showed how the L2 speaker began to take a more central role in co-constructing the activity: The L1 speaker's repeated use of decision-making moves (e.g., *Jaa sore ni shiyoo* 'Then let's decide on it') made clear the interactional function of the prior *ne*-marked assessment (e.g., *Ii ne* 'It's good, isn't it?') and the positive response to it (e.g., *Un* 'Yeah') as the precursor to a decision-making move, and the L2 speaker was later able to use decision-making moves in this sequential position.

Evaluation and Prospects

While systematic investigations of L2 pragmatic development have begun only since the mid-1990s, this research area has grown at a fast pace. The scope of research on pragmatic competence and its development has expanded from a centralized focus on speech act performances to interactional competences and negotiation of one's identity in the TL community. By importing various methodologies and drawing on theories from relevant disciplines, L2 developmental pragmatics research has produced a considerable amount of important findings: routes of pragmatic development and its relationship with the development of grammatical competence, and factors affecting the developmental processes including one's L1 pragmatic competence, noticing of relevant input, availability of corrective feedback, types of instruction, types and amount of input, one's positionality in the TL community, and various configurations of social interaction in which one recurrently participates.

Adjustment and innovation of research methodology have also taken place. While written responses to discourse-completion tasks constitute an effective data set for comparing different groups of participants, more developmental studies that utilize audio- and video-recorded data of spontaneous interaction have been conducted to enable meticulous analysis of L2 speakers' pragmatic actions contingent to the ongoing process of interaction. Around the mid-2000s, when Kasper (2006) called for studies on discursive pragmatics, a small

number of developmental studies began to appear that analyzed L2 speakers' pragmatic competence as it manifested itself within sequential contingencies. For example, through conversation analysis of post-instruction interactions in his classroom study of instructional effect on compliment responses, Huth (2006) documented an L2 speaker's spontaneous L1-based response and her immediate repair with a TL-like one. His analysis suggests the potential of conversation analysis to reveal the relationship between L2 pragmatic knowledge and the level of processing control, which was raised by Bialystok (1993).

The issue of resistance to TL norms constitutes another object of inquiry in the L2 pragmatic development research. So far, L2 speakers' choice to deviate from perceived TL norms has been identified first by detecting differences between L1 speakers' and L2 speakers' performances, and then by extracting L2 speakers' self-report on their language use. However, some researchers began to document the ways in which their identity struggle is manifested in the actual interaction. Huth's (2006) study provides an excellent example of how L2 speakers' resistance to performing a TL-like speech act was found in their use of a high pitch and laughter, which indicated their consideration of compliment responding as a staged performance. Since the act of resistance and the activity of negotiating identity involve one's pragmatic competence, the changes in the ways in which L2 speakers negotiate their identity with the use of L2 linguistic resources will figure as an important object of investigation in developmental L2 pragmatics research.

Another issue that could be further investigated is the mechanism of learning in non-pedagogical contexts of language use. While instructional intervention studies have demonstrated the effectiveness of drawing students' selective attention to particular L2 practices and promoting inductive learning, such instruction is usually not provided to L2 speakers living in the TL community. The question arises as to what kind of interactional processes help them achieve higher pragmatic competence without instructional intervention. L2 developmental research on pragmatic competence has the potential to further the understanding of how relevant L2-specific practices can be made salient for L2 speakers to notice and how effective feedback on their pragmatic actions can be provided. Such understanding could also have practical implications for language educators.

Second Language Reading, Scripts, and Orthographies

KEIKO KODA

Reading has several unique properties. One such property is the universal dependence of writing systems on language. According to the “Universal Grammar of Reading” (Perfetti, 2003), writing systems encode spoken language and as such, do not represent meaning directly independent of language, necessitating language in decoding and encoding meaning in print. Reading thus is the dynamic pursuit embedded in two interrelated systems—a language and its writing system—and its acquisition requires making links between the two systems. Inevitably, learning to read entails systematic deductions at two levels: the general mapping (uncovering *which language element* is directly encoded in each graphic symbol) and the mapping details (unpacking *how* the symbols are used to encode spoken words).

When literacy learning occurs in a second language (L2), the demands for the required linkage building increase exponentially. Unlike monolingual first language (L1) reading, L2 reading is crosslinguistic, involving two languages in virtually all of its operations. Because each instance of L2 learning to read comprises a distinct combination of languages, the mapping requirements vary both within and across learner groups. L2 reading is further compounded by additional sources of variances as it encompasses a wider range of learners, including those of different ages and with diverse language backgrounds, than does L1 reading. L2 reading research must take into account these multiple diversities and the resulting complexities uniquely associated with L2 reading development. This entry describes (a) how orthographic knowledge contributes to learning to read, (b) how this knowledge varies across languages, and (c) how the knowledge acquired in one language affects learning to read in another language.

In this entry, the term, *writing system*, is used in reference to both the writing system of a language and an abstract type of writing system. In the latter sense, writing systems can be classified into three types: alphabetic, syllabic, and logographic (Coulmas, 2003). In the alphabetic system, each symbol represents a phoneme, while, in the syllabary, individual symbols denote distinct syllables. In contrast, a logographic character corresponds holistically to the meaning and sound of an entire morpheme. Within each system, considerable variations exist in the specific details in which graphic symbols are physically placed in encoding spoken words. *Orthography* refers to these language-specific details, and has been defined as “the standardized variety of a given, language-specific, writing system” (Coulmas, 2003, p. 35). Finally, the term *script* refers to the graphic form of the symbols of a writing system. To illustrate, English and Russian writing systems are both alphabetic, but they differ in their scripts—the former employs the Roman script and the latter uses the Cyrillic. English and Spanish are alphabetic, both employing the Roman script, but differ orthographically in spelling conventions.

Role of Orthographic Knowledge in Learning to Read

Although linkage building (making links between language and print) is universally required for learning to read, how it is accomplished differs considerably in typologically

diverse languages. To uncover the general mapping principle in English, for example, children must understand that each letter represents a distinct sound—either a consonant or a vowel—and then gradually work out the details of sound–symbol correspondences. In contrast, children learning to read Chinese must first realize that each graphic symbol (character) corresponds to the meaning and sound (single syllable) of one whole morpheme and subsequently, learn how individual characters are combined to form compound characters.

In learning the mapping details, children must deduce the specific way in which graphic symbols are used to represent spoken words. The skills optimal for the required mappings are shaped to accommodate the specific features of the grapheme–language relationships in the orthographic system employed in a particular language. Korean and Hebrew writing systems, as an illustration, are both alphabetic, but their orthographic properties differ considerably. The Korean Hangul, as a case in point, consists of 24 basic symbols, each representing a single phoneme—either a vowel or a consonant. Unlike English, however, the Korean symbols do not appear individually; rather, they must be packaged into square blocks, representing distinct syllables. Reflecting the dual-level representation, Korean children exhibit strong sensitivity to both syllables and phonemes (Cho & McBride-Chang, 2005). In contrast, the Hebrew symbols represent only consonant phonemes (Shimron, 2006). Hebrew vowels are shown in the form of dots and dashes, and placed below, above or to the left of symbols. In the consonantal Hebrew, children develop stronger sensitivity to consonants than vowels (Geva, 2008). In order to explore long-term effects of literacy experience in one language on learning to read in another, it is essential to clarify the method of identifying the facets of *orthographic knowledge* critical for the required grapheme-to-language mappings, and variation therein, across a wide range of languages.

Development of Orthographic Knowledge

Current psycholinguistic theories hold that learning involves detecting, abstracting, and internalizing structural regularities implicit in input. Input exposure and experience therefore are the key determinants of learning outcomes—that is, what is learned and how well it is learned. In this view of learning, *orthographic knowledge* is defined as an elaborate matrix of correlations among graphemes, phonemes, syllables, and morphemes (Seidenberg & McClelland, 1989), and the resulting associative networks linking these constituent elements emerge through cumulative grapheme-to-language mapping experience (Adams, 1990). The more frequently a particular pattern of mappings are experienced, the stronger the linkages that hold the elements together. Ultimately, it is the strength of these linkages that supports speedy and effortless mappings. The internalization of a particular pattern of mappings is recognized as such when the mappings are executed through automatic (nondeliberate and nonvolitional) activation triggered by print input (Logan, 1988).

Under this view of learning, crosslinguistic variation in orthographic knowledge occurs in two dimensions: (a) the linguistic information directly encoded in each graphic unit and (b) regularity in grapheme-to-language correspondences. Such variation was tested in early experimental studies employing a variety of word recognition tasks. Their results showed that phonological and graphic manipulations induce different responses in readers of contrasting (alphabetic and logographic) writing systems (Frost, Katz, & Bentin, 1987; Hatta, 1992). Clinical observations of Japanese aphasics also revealed that two types of Japanese aphasic patients (those with Kana or Kanji impairment) have lesions in different areas of the brain, and thus provide further support for the hypothesis that typologically diverse writing systems require different neurological processing (Sasanuma, 1984; Hayashi, Ulatowska, & Sasanuma, 1985). By means of neuroimaging, moreover, recent studies have identified unique patterns of neural activation for reading printed words in alphabetic and logographic writing systems (Bialystok & Luk, 2007; Perfetti et al., 2007).

The psycholinguistic grain size theory (Ziegler & Goswami, 2006) offers a plausible explanation of how the observed variation in decoding behaviors relate to varying consistency in symbol-to-sound correspondences both within and across writing systems. Children initially develop sensitivity to larger phonological units in speech and gradually refine their sensitivity to distinguish smaller units. Although the sequence of phonological development is similar across languages, the precise ways in which spoken sounds are mapped onto graphemes vary across writing systems. In learning to map, children must understand the most effective grain size for achieving decoding efficiency in their writing system. According to the theory, the optimal grain size in each writing system is determined by the amount of orthographic information required for decoding. In phonologically transparent orthographies, decoding necessitates little orthographic information. The grain sizes required for decoding in these systems are small at the phonemic level. In contrast, in phonologically opaque orthographies, decoding demands far more orthographic information, and thus, necessitates larger grain sizes, such as syllables, rimes, and even morphemes.

L2 Reading Development

Dual-language involvement, as noted above, is a major characteristic of L2 reading. Once established in one language, reading skills transfer across languages, and are incorporated in learning to read in another language. Research has shown that transferred L1 skills alter the manner and the rate in which a new set of skills are shaped in a later acquired language (Wang, Koda, & Perfetti, 2003; Hamada & Koda, 2008; Das, Padakannaya, Pugh, & Singh, 2011). Multiple diversities are another characteristic as L2 reading encompasses a wide range of learners, including those of different ages and with divergent L1 backgrounds. The clear implication is that the cognitive and linguistic foundations vary across diverse learner groups to a greater extent than those typically assumed to exist among beginning L1 readers. Hence, L2 reading development is inherently more complex and diverse than monolingual L1 reading development. L2 reading research has examined how L2 reading acquisition varies among cognitively and linguistically diverse L2 learners.

Integral to this research is the notion of crosslinguistic transfer. Within the input-driven view of learning, transfer is defined as automatic activation of L1 mapping patterns triggered by L2 print input (Koda, 2008). For transfer to occur, the skills in question must be well rehearsed—to the point of automaticity—in the first language. Well-established L1 skills, transferred through automatic activation during L2 reading, are operative when learning to read in an L2, and as a result, L2 mapping skills evolve through crosslinguistic interaction between transferred L1 skills and emerging L2 orthographic knowledge. Under these premises, three factors are central to L2 reading skills development: (a) L1 orthographic knowledge, (b) L2 orthographic knowledge, and (c) similarity between L1 and L2 orthographic properties.

L1 Orthographic Knowledge

In exploring the impacts of prior reading experience, a growing number of studies have investigated how corresponding reading skills between two languages are related through batteries of tasks designed to measure a range of reading subskills, including phonological awareness (Durgunoglu, Nagy, & Hancin, 1993; Bialystok, McBride-Chang, & Luk, 2005; Wang, Perfetti, & Liu, 2005), morphological awareness (Saiegh-Hadd & Geva, 2008) and decoding (Durgunoglu et al., 1993; Geva & Siegel, 2000). Collectively, these studies have established crosslinguistic relationships in a small, but critical, set of subskills across diverse combinations of first and second languages in biliteracy development.

From a language-specific perspective, other studies involving adult L2 learners have examined whether L1 orthographic properties explain variations in L2 decoding behaviors

among L2 learners with diverse L1 orthographic backgrounds. Inasmuch as the critical contrast between alphabetic and logographic literacy lies in the relative reliance on phonological and graphic information during decoding, in these studies, L2 stimulus words were manipulated *either* phonologically (e.g., blocking phonological information by replacing words with unpronounceable symbols, such as 𐄂 𐄃; Koda, 1990) or graphically (e.g., creating visual distortion by replacing real words, such as “read,” with their case altered version “ReAd”; Akamatsu, 1999), and the magnitude of the manipulation employed was compared among L2 learners with contrasting L1 backgrounds. Their data demonstrated that diverse L2 learner groups responded differently to the two types of manipulation (Green & Meara, 1987; Koda, 1998; Akamatsu, 1999) and that the reported differences were identifiable with the orthographic properties of the participants’ respective first languages (Koda, 1990, 1993; Ryan & Meara, 1991). Viewed together, these findings suggest that previously acquired L1 mapping skills are involved in L2 reading development, systematically altering L2 decoding behaviors.

More recent studies have directly compared the relative impact of L1 and L2 orthographic knowledge on L2 decoding performance. To isolate the impact stemming from each language involved, L2 stimulus words were manipulated *both* phonologically *and* graphically within each study, using a wide range of tasks, including semantic category judgment (Wang, Koda, et al., 2003), associative word learning (Hamada & Koda, 2008, 2010), and word identification (Wang & Koda, 2005). In such a design, the extent that a particular manipulation affects both groups is used as a basis for gauging the L2 orthographic impact, and the extent that the effect of the manipulation varies between the groups serves as an index of L1 orthographic impact. Their data generally suggest that proficiency-matched L2 learner groups are similarly sensitive to L2-specific orthographic properties; that learners with contrasting L1 orthographic backgrounds rely on phonological and graphic information in varying degrees during L2 decoding; and that L2 properties have a much stronger impact on L2 decoding skills formation, overriding the variance attributable to L1 properties.

L2 Orthographic Knowledge

As the key determinants of learning outcomes, input exposure and experience play a vital role in the acquisition of reading skills. Analysis of input properties thus is vital in explaining how the required mappings are acquired in a particular language, and how the resulting skills vary across languages. Despite its obvious significance, little information is available on the nature of L2 print input and its impact on L2 reading development. Of late, however, preliminary efforts are underway to explore how specific input properties enhance the initial stages of learning to read in a second language.

Wang, Perfetti, and Liu (2003) examined how curriculum-based input frequency affects character knowledge development among native English-speaking learners of Chinese. Using a lexical decision task, the researchers found that these learners were capable of detecting structural violations even after one semester of studying Chinese; and that a notable portion of performance variance was accounted for by the frequency of the target characters. These findings imply that adult L2 learners are quickly sensitized to the major structural properties of a new writing system; and that print input frequency greatly enhances the formation of such sensitivity.

The impact of print input and exposure has also been studied with school-age students learning to read Chinese as a heritage language (CHL) (Koda, Lu, & Zhang, 2007). The researchers analyzed the properties of the Chinese characters introduced in Grade 1 through 6 textbooks specifically designed for CHL learners. Based on the analysis, they then measured the students’ sensitivity to the identified properties. Their data demonstrated that different facets of morphological sensitivity matured in different degrees in CHL learners;

and that the different maturational rates were systematically related to structural transparency and functional salience of the instructed characters. Taken together, these initial findings suggest that L2 input characteristics play a decisive role in explaining how L2 reading skills are shaped and utilized.

Distance Between L1 and L2 Orthographic Properties

Orthographic distance refers to the degree of similarity between the orthographic properties of two languages. Because combinations of languages are at variance across L2 learner groups, orthographic distance differs in each instance of L2 reading acquisition. When L1 and L2 orthographic systems share similar properties, transferred L1 mapping skills are readily available in the new language without any substantial adjustment. In contrast, when the two are typologically distinct, substantial modifications are necessary for transferred skills to be functional in L2 print information processing. Orthographic distance thus is an additional source of variance in grapheme-to-language mapping skills among L2 readers with related and unrelated L1 orthographic backgrounds. Although distance effects have been widely acknowledged, little has been explored as to how shared structural properties facilitate L2 reading development.

Muljani, Koda, and Moates (1998) shed substantial light on the issue by testing orthographic distance effects on L2 intraword structural sensitivity. Comparing lexical decision performance among proficiency-matched adult ESL learners with related (Indonesian employing a Roman alphabetic script) and unrelated (Chinese using a logographic system) L1 orthographic backgrounds, the researchers found that only Indonesian participants benefited from intraword structural congruity (i.e., spelling patterns consistent between English and Indonesian), but their superiority was far less pronounced with structurally incongruent items whose spelling patterns were not shared with either L1. The findings would seem to suggest that although orthographic similarity has a general facilitative impact, accelerated efficiency is more localized than has been thought, occurring only for the operations whose demands are analogous, if not identical, between two languages.

Similar findings have been reported in studies comparing grapheme-to-morpheme mapping efficiency among L2 learners of English (alphabetic, concatenative) with related (Korean: alphabetic, concatenative) and unrelated (Chinese: logographic, non-concatenative) L1 backgrounds (Koda, Takahashi, & Fender, 1998; Koda, 2000). Not surprisingly, Korean learners were more efficient in morphological segmentation and analysis than their proficiency-matched Chinese counterparts, but the efficiency gap was substantially reduced when the groups were confronted with the items whose structural properties are unique to English. Here again, the findings suggest that the distance effect is far more specific and localized than has been generally assumed.

In brief, the studies investigating crosslinguistic interaction, though still limited in quantity, suggest that L1 reading experience has long-lasting impacts on L2 reading development, explaining a significant portion of the variance in mapping efficiency in proficiency-matched, but linguistically diverse, L2 learners. L1-induced variance is less evident, however, in the items whose features are specific to the target language. Hence, it appears that the formation of L2 mapping skills is guided by insights stemming from both L1 and L2 orthographic properties, but L2 input is the dominant force in shaping those skills in the new language.

To summarize, as the dynamic pursuit embedded in a language and its writing system, reading requires making links between two systems, and its acquisition entails systematic deductions of how spoken language elements are mapped onto the unit of graphic symbols that encode them. The skills optimal for the requisite grapheme-to-language mappings therefore vary across languages. In L2 reading research, the critical question is how orthographic knowledge acquired in one language influences the formation of the

grapheme-language mapping skills in another language. Cumulative evidence suggests that L2 mapping skills emerge through crosslinguistic interaction between transferred L1 skills and L2 print input. L1 and L2 orthographic knowledge thus both contribute substantially, though in distinct manners, to L2 reading development.

Second Language Representation in the Brain

JUBIN ABUTALEBI AND MEIYUN CHANG-SMITH

Introduction

Second language (L2) representation in the brain refers to the neurolinguistic and neuroscientific study of the cerebral organization of multiple languages in the human brain. From early accounts of selective loss and recovery in bilingual aphasia (i.e., loss of language due to a brain lesion) to recent brain imaging studies, issues inherent in the neurolinguistics of bilingualism have inspired researchers for more than a century. Investigations into the neural basis of bilingualism focus not only on how two languages are represented in the brain (i.e., the anatomical locations) but also on how these languages are processed by the brain. One general assumption is that processing of a supposedly “weaker” L2 may occur via different mechanisms from those that mediate processing of the underlying, “stronger” first language (L1). In this entry, after a brief historical overview, we will illustrate findings inherent in the representation of L2s, followed by a section focusing on bilingual language processing.

Historical Overview

The first scientific approach to studying L2 representation was the study of bilingual aphasics. Several clinical aphasia studies have shown that bilingual aphasics do not necessarily manifest the same language disorders with the same degree of severity in both languages. In some cases, the L1 is recovered better than the L2. In other cases, the converse pattern is manifested. Since the landmark study in 1895 by the French neurologist Pitres, who was the first to draw attention to the frequently differential rates of language recovery following aphasia in bilinguals, many different recovery patterns have been described. These include selective recovery of a given language (i.e., one language remains impaired while the other recovers); parallel recovery of both languages; successive recovery (i.e., after the recovery process has taken place for one language, the other language follows); alternating recovery (i.e., the language that has first recovered will be lost again due to the recovery of the second language); alternating antagonistic recovery (i.e., on one day the patient is able to speak in one language while the next day only in the other); and pathological mixing of the two languages (i.e., the elements of the two languages are involuntarily mixed during language production). The study of bilingual aphasia is important because it indicates the cortical regions necessary for performance of a linguistic task (e.g., speaking in L1).

At present, however, we lack a causal account for the various recovery patterns and hence cannot predict clinical outcomes. Concerning the possible factors involved, no correlation has been found between the patterns of recovery and neurological, etiological, experiential, or linguistic parameters: neither site, size nor origin of lesion, type nor severity of aphasia, type of bilingualism, language structure type, nor factors related to acquisition or habitual use.

Theoretical conjectures arising from studies of bilingual aphasia developed along two distinct lines: a more traditional approach and a more dynamic one. The more traditional “localizationist” view argued, for instance, that the specific loss of one language would occur because the bilingual’s languages are represented in different brain areas or even in different hemispheres. Hence, a focal brain lesion within a language-specific area may impact only on that specific language while leaving the other language intact. In contrast, according to the “dynamic” view, selective recovery arises because of compromises to the language system rather than damages to differential brain representations. A selective loss of a language arises because of increased inhibition, that is, because of a raised activation threshold for the affected or lost language or even because of an imbalance in the means to activate the language because of the lesion. Following this view, a language is not destroyed by the lesion but temporarily inaccessible. It is worth noting that Pitres’s proposal was for a “dynamic” explanation of language recovery in bilingual aphasics: Language recovery could occur only if the lesion had not entirely destroyed language areas, but only temporarily inhibited them through a sort of pathological inertia. According to Pitres, the patient generally first recovered the language to which she or he was predominantly exposed (which may not necessarily be the native language) because the neural elements subserving “the more exposed language” were more strongly consolidated in the brain.

A large number of reported recovery patterns in bilingual aphasia may be explained by the dynamic view. As postulated by Paradis (1998), a parallel recovery would then occur when both languages are inhibited to the same degree. When inhibition affects initially only one language for a period of time and then shifts to the other (with disinhibition of the prior inhibited language), a pattern of alternating antagonistic recovery occurs (see Green, 1986). Selective recovery may occur if the lesion has permanently raised the activation threshold for one language. Finally, pathological mixing between languages would occur when languages cannot be selectively inhibited any more.

In general, the aphasia data have provided a rich source of evidence on the range of language disorders and language recovery patterns in bilinguals. However, there are limitations to the generalizability of such data to neurologically healthy individuals. Concerns about the lesion-deficit approach include the inability to determine whether specific language deficits are the result of damage to a specialized language component at the lesion site, or whether the damaged area is simply part of a larger neural network that mediates a given component of language. Likewise, aphasia data do not allow us to separate effects of injury from those of neural plasticity or a reallocation of healthy cortical tissue for the mediation of language functions lost as a result of brain injury. Nevertheless, studying the effects of brain damage on linguistic function in bilinguals has led to a number of interesting observations about the nature and course of language impairment and recovery, which in turn has stimulated researchers to apply functional neuroimaging techniques to investigate bilingual language processing at a more fundamental level.

The Neural Representation of L2

In order to successfully learn an L2, a whole new set of phonological, lexico-semantic, and morphosyntactic knowledge, distinct from the L1, needs to be stored and mentally instantiated. Whereas for L1 acquisition, the shaping and organization of such knowledge usually lead to a fairly effortless tuning of all cognitive processes subtending language, the same phenomenon hardly ever occurs for an L2 learned after early childhood. An important question to unravel is whether L2 learning is constrained by the “critical” time period which is paralleled in neural terms by maturational changes in the brain (McDonald, 2000).

Although it has been clearly demonstrated that successful L1 acquisition can occur only during a certain age span, the same may not necessarily hold for L2 learning. L1 acquisition and L2 learning show clear dissimilarities with respect to the learning processes and the mastering of various components of language. Only in the rare case of simultaneous double L1 acquisition from birth (or from very early childhood) can one see fully balanced acquisition (Chang-Smith, 2009, 2010).

Researchers have hypothesized a “fundamental difference” between L1 acquisition and L2 learning. An influential position, namely the critical-period hypothesis (CPH; Johnson & Newport, 1989; Birdsong, 2006) claims that there is a critical period in acquiring full competence (phonological, lexico-semantic, and morphosyntactic representations) in two (or more) languages. Despite the rapid developments in cognitive neuroscience since the early 2000s, the neurocognitive basis of L2 learning and processing is still not well understood. For example, there is still no firm consensus about how L2 learners comprehend or produce language in real time.

Neural Representation of L2 Grammar

The CPH postulates the existence of a critical period for acquisition of segmental phonology, inflectional morphology, and syntax. Changes to the human language faculty (or language acquisition device) induced by neural maturation are postulated to constitute the basis of the substantial differences between L1 speakers and L2 learners in the acquisition and attainment of grammatical competence (Johnson & Newport, 1989; Birdsong, 2006).

The declarative/procedural model (DP; Ullman, 2001) provides a rationale for the supposition of differential representation by claiming that in normal monolinguals, words are represented in a declarative (i.e., explicit) memory system whereas grammatical rules are represented in a cognitive system that mediates the use of procedure memory (i.e., implicit memory that is processed without conscious awareness). When an L2 is learned after the critical period, it cannot rely on the implicit resources that are used for L1 grammatical processes, and thus grammatical processing in the L2 would be carried out by explicit resources. However, with increased proficiency, aspects of grammar might become increasingly dependent on procedural memory (Ullman, 2001). Since implicit and explicit knowledge are mediated by distinct neural systems (i.e., Broca’s area and the basal ganglia for the first type and left temporal areas for the second), late L2 learners would use different and more posterior brain areas (left temporal areas) than would L1 speakers (Broca’s area and the basal ganglia) whenever they compute L2 grammar (Ullman, 2001).

In contrast to Ullman’s view, Green (2003) argues instead that L2 learning arises in the context of an already specified, or partially specified, language system (i.e., L1). According to the convergence theory (CT; Green, 2003), if Broca’s area has learned to compute grammatical processing for the L1 during the initial stages of language acquisition, it will perform the same kind of computation also for an L2. Differences may arise in the initial stages of L2 learning, where additional brain areas for processing the newly learned L2 are required, but once an L2 reaches a comparable degree of proficiency, its neural representation will converge toward that of the L1 (Broca’s area and basal ganglia in the case of grammar processing).

A strong source of evidence in favor of the CT comes from studies of artificial grammar learning. In a landmark study, Opitz and Friederici (2004) investigated with functional magnetic resonance imaging (fMRI) the acquisition of language-like rules of an artificial language. Increased proficiency in the artificial language was associated with increased recruitment of Broca’s area. In a further study, Friederici, Bahlmann, Helm, Schubotz, and Anwander (2006) confirmed those findings. These results support the notion that learning L2 grammar (albeit an artificial one) is achieved through an existing network mediating

syntax in the L1. In more naturalistic settings (i.e., studies investigating bilinguals) the available evidence clearly points out that both low and highly proficient bilinguals engage for an L2 the same neural structures responsible for L1 grammatical processing. For example, studies investigating single word processing in an L2 such as verb conjugation (Sakai, Miura, Narafu, & Muraishi, 2004) and past tense word processing (Tatsuno & Sakai, 2005) showed increased activity around the areas mediating L1 syntax (i.e., Broca's area). Furthermore, Sakai et al. (2004) showed that the acquisition of grammatical competences in late bilingual twins is achieved through the same neural structures for processing L1 grammar. Such findings appear to be inconsistent with the direct application of the DP model to the bilingual case because the model proposes that the basal ganglia are not involved in syntactic encoding in L2.

In summary, these studies show us that the same set of brain areas responsible for the acquisition and processing of L1 grammar is also involved for those of L2, independently of age of L2 acquisition and proficiency. Second, there may be differences regarding the extent of brain activity in the sense that L2 processing (with a lower degree of proficiency) would entail additional areas located around Broca's area (but not in posterior brain areas as suggested in Ullman, 2001). Third, the differences in the extent of brain activity seem to vanish once the proficiency is comparable to that in the L1; hence the neural representation of the L2 converges to that of the L1 as suggested by Green (2003). However, it remains to be determined why exactly there is more activity for an L2 (especially when spoken with a low or non-native-like proficiency) in Broca's area and surrounding areas. Following Indefrey (2006), it might be that bilinguals compensate for lower efficiency by driving this region more strongly.

Neural Representation of L2 Phonology

Languages differ in many properties, including their phoneme inventories. Correctly perceiving and producing the sounds of an L2 is a challenging task, as evidenced both by widespread anecdotal evidence and by a number of formal studies. Problems of this kind are observed even for those who have been exposed to an L2 for considerable periods of time and hence have had plenty of opportunities to learn its sounds (Pallier et al., 1997). In the same way as for syntactic processing, critical or sensitive periods have been postulated also for phonological processing (Singleton, 2005).

From a neuroanatomical perspective, monolingual phonetic perception and production appears to involve specialized networks in the left hemisphere—the major areas involved are Wernicke's area in the left temporal lobe, the supramarginal and angular gyrus in the parietal lobe, and also Broca's area in the frontal lobe, as shown by functional neuroimaging of both adults (see, for a review, Démonet, Thierry, & Cardebat, 2005) and young infants (Dehaene-Lambertz et al., 2002). Recent neuroimaging studies also provide evidence for a shared neural network for L1 and L2 phoneme perception and production (e.g., Heim & Friederici, 2003). The temporal dynamics in this network during phoneme perception shows a primacy of Wernicke's over Broca's area, while the reversed pattern occurs during production. Heim and Friederici (2003) interpreted this finding with respect to the functionality of the different regions within the shared network, with Wernicke's area being the storage of sound forms and Broca's area the processor necessary to extract relevant phonological information from the sound storage.

We may again pose the question as to whether L2 phonological representations are acquired, stored, and processed in a different manner from those of the L1 at the brain level. A series of studies specifically investigating phonological processing are now available in the literature. For instance, Callan, Jones, Callan, and Yamada (2004) investigated the neural processes underlying phoneme perception using the fMRI method. The same set of phonemes (i.e., English syllables starting with /r/, /l/, or a vowel) were tested on

native English speakers and low-proficiency Japanese L2 learners of English. Greater neuronal activity for L2 compared with L1 speakers of English during perceptual identification of /r/ and /l/ relative to vowels was observed in Broca's area, Wernicke's area, and parietal areas (including the supramarginal gyrus). Conversely, more extended activity for L1 English speakers was found in the anterior parts of the temporal lobe. For L2 English speakers, Callan et al. (2004) suggested that the more extended involvement of neural structures for non-native phoneme identification may be related to the use of internal models of speech articulation and articulatory-oro-sensory representations that are used to overcome the difficulty in L2 phoneme identification.

In summary, although the functional neuroimaging literature on phonological processing in bilinguals is rather limited (as compared to the multitude of studies investigating morphosyntactic and lexico-semantic processing), some tentative conclusions may be drawn: the available evidence shows that L2 phonology, like grammatical processing, is essentially acquired and processed through the same neural structures mediating that of the L1. As to the extension of brain activity, studies indicate that overall L2 processing is in need of greater recruitment of neural resources. One reason for this observation might be that many studies have used late and low-proficiency L2 learners (i.e., Callan et al., 2003; Wang, Sereno, Jongman, & Hirsch, 2003; Callan et al., 2004), or monolingual subjects who, for the experimental purpose, were asked to learn phonetic contrasts in a foreign language (Golestani & Zatorre, 2004). In the latter case, it is possible that the greater brain activity may reflect the accommodation of a new set of sounds by the existing native speech system rather than the acquisition of a non-native phonetic contrast in an L2 context. In the former case (i.e., L2 English speakers), it is plausible that processing sounds in the L2 is subserved by less well-tuned neural representations, or may require greater cognitive effort, or both, and therefore requires greater neuronal activity than processing sounds in the L1.

Neural Representation of L2 Lexico-Semantics

In the context of the multilingual brain, many studies have addressed the question of whether the neuroanatomical organization of the bilingual mental lexicon may also be affected by neural maturation. One class of models delineates two different levels of representation within the architecture of the bilingual's memory that are "hierarchically" related (Potter, Von Eckardt, & Feldman, 1984). For example, the revised hierarchical (RH) model (Kroll & Stewart, 1994) claims that separate lexical memory systems contain words for each of the two languages, whereas concepts are stored in an abstract memory system common to both languages. At the early stage of L2 development, L2-L1 mediation mainly occurs between translations at the lexical level; with further L2 development (i.e., for highly proficient late bilinguals), L2 lexical codes become more tightly bound to their specific conceptual representations.

By contrast, the other class of models, including the bilingual interactive activation model, postulates three levels of representations (Dijkstra & van Heuven, 2002; see also the interactive model proposed by Silverberg & Samuel, 2004). The lexical level contains words, and "above" them at the conceptual level (lemma level) their meanings are represented, whereas "below" them their orthographic and phonological features (letters and phonemes) are represented at the lexeme level.

The "hierarchical" and the "interactive" models put forward different hypotheses concerning the relationship between the age of acquisition (AOA) of an L2 and the shaping and nature of the semantic conceptual representations for L1 and L2 words, although both models postulate that the L1 and L2 share common conceptual representations, irrespective of the AOA of the L2. In contrast, Silverberg and Samuel (2004) claim that only for early bilinguals will common semantic representations cluster at the conceptual level. However, higher levels of L2 proficiency enable lexical-semantic mental representations more closely

resembling those constructed in the L1. According to Green's CT (2003), many of the qualitative differences between native and L2 speakers may disappear as proficiency increases.

Irrespective of the experimental paradigm employed (such as picture naming, verbal fluency, word completion, and word repetition), functional neuroimaging studies consistently reported common neural activations in similar left frontal and temporo-parietal brain areas, when the degree of L2 proficiency was comparable to that in the L1 (see, for reviews, Indefrey, 2006; Abutalebi, 2008). It is noteworthy that the same set of areas are commonly engaged when monolinguals perform the same tasks. The fact that the observed activation patterns for L2 lexical retrieval were found to be similar, if not identical, to those for the L1 with the same individuals indicates that a bilingual can utilize the same neural structures to perform identical tasks for both languages. Moreover, this happened irrespective of differences in orthography, phonology, or syntax among languages (Chee, Tan, & Thiel, 1999). On the other hand, bilinguals with low proficiency in the L2 engaged additional brain activity, mostly in prefrontal areas (Indefrey, 2006; Abutalebi, 2008). It is also worth mentioning that these findings were confirmed by employing experimental paradigms such as lexical decision and semantic judgment tasks in bilinguals (Abutalebi, 2008). Indeed, low-proficiency bilinguals activated the prefrontal cortex more extensively.

In summary, functional neuroimaging studies illustrate that an L2 is processed essentially through the same neural networks underlying L1 processing. L2-related differences are found for low-proficiency and/or less exposed bilinguals in terms of greater engagement of the left prefrontal cortex or the selective engagement of prefrontal areas located outside the classic language areas (more anterior to language areas).

Neural Dynamics of L2 Processing

How may we interpret the overall finding of greater engagement of the left prefrontal cortex during L2 processing (i.e., if mastered in a not yet native-like fashion), not only in lexical tasks but also, as shown above, during grammatical and phonological tasks? It has been proposed that activity within the prefrontal cortex may reflect executive control over access to short- or long-term memory representations such as grammatical, phonological, or lexical representations to assist L2 processing (Abutalebi & Green, 2007; Abutalebi, 2008).

This leads us finally to discuss one of the most salient and unique aspects of bilingualism, namely "language control." Language control refers to the ability of bilinguals to suppress one language while speaking the other. Indeed, language competition is resolved by actively inhibiting the so-called "non-target language." Consider the fact that individuals can perform different actions as a result of the same stimulus. For instance, a bilingual can name a presented word in the L1 or translate it into the L2. The task goal must be maintained in the face of conflicting goals and the various actions required to perform the task must be coordinated (e.g., retrieve or compute the word's phonology from its spelling or retrieve the meaning of the word and select its translation). Once a given task is established, however (e.g., speaking in the L2), competition with alternative possible tasks (speaking in the L1) may be resolved more automatically. Where individuals wish to alter their goal (for example, to switch from speaking in one language to speaking another), they must disengage from the current goal and switch to the new goal.

Psycholinguistic evidence points to the fact that such interference is more common when speaking a weak L2. In that case, for example, when asked to name a picture in the L2, the bilingual speaker has to inhibit the L1 in order to prevent interference. Functional neuroimaging studies using experimental tasks like picture naming, switching, translating,

and so forth have elegantly shown that these tasks are accompanied by the activation of brain areas that are not directly linked to language representation but rather to executive control (such as the left prefrontal cortex, the left caudate nucleus, and the anterior cingulate cortex; Abutalebi et al., 2007). The engagement of these areas is obviously more relevant when subjects have to process a weak L2 (Abutalebi et al., 2008). The functions generally ascribed to the prefrontal cortex comprise working memory, response inhibition, response selection, and decision making, while the left caudate was reported to be important for language selection and set switching. The anterior cingulate cortex is related to functions such as conflict monitoring, attention, and error detection. It becomes clear that the engagement of these structures provides a cerebral testimony of the cognitive processes inherent to bilingual language processing: competition, and control between languages.

In contrast, a “strong” L2 system (i.e., an L2 in which the speaker is highly proficient) is processed in a more native-like fashion and, hence, in a more automatic manner without the engagement of brain areas related to cognitive control.

Conclusions

What we may conclude is that, first of all, the long-held assumption that the L1 and L2 are necessarily represented in different brain regions or even in different hemispheres in bilinguals is not confirmed by neuroimaging studies. On the contrary, there is ample evidence that the L1 and L2 are processed by the same neural structures. The patterns of brain activity associated with grammatical, phonological, and lexical processing are remarkably consistent among different languages that share the same brain language system. These relatively fixed brain patterns, however, are modulated by a number of factors, chief among which is the degree of L2 proficiency. The complex process of L2 acquisition may be considered as a dynamic process, requiring additional neural resources (i.e., more brain activity) in the early stages. These additional neural resources are mostly found within the left prefrontal cortex, the left basal ganglia, and the anterior cingulate cortex, and seem to be associated with the greater control demand when processing a “weaker” L2 (Abutalebi, 2008). Once the L2 learner gains sufficient L2 proficiency, its processing becomes more automatic and less in need of those additional neural resources. At this stage one may suppose, in concert with existing psycholinguistic evidence (Kroll & Stewart, 1994), that the L2 is processed in the same fashion as the L1.

Second Language Speech Perception and the Brain

YUE WANG

The theoretical framework of second language (L2) speech perception and processing is based on the nature–nurture interplay in language learning. Theories have traditionally been dominated by the critical-period hypothesis (CPH), which suggests a maturation-based constraint in learning, resulting from the loss of plasticity of the brain after puberty. Current views posit that L2 speech learning is influenced by linguistic experience, as later learning may be constrained by initial exposure to a native language (L1). Nevertheless, speech learning can improve as learners gain experience in the L2, as the mature human brain is believed to remain malleable. While the nature–nurture issues cannot be framed in all-or-none dichotomies, the debate is still current as to the extent to which speech processing and learning are influenced by linguistic experience, or reflect lower-level encoding of physical properties, as well as the extent to which they involve an interconnected system within the realm of cognitive processing. Specifically, research in L2 speech processing and learning has addressed these issues from three perspectives: (a) whether the processing of L2 speech employs specialized neural substrates and how it is influenced by experience with an L1 speech system; (b) how learning-induced plasticity is instantiated in the brain; and (c) how L2 speech learning patterns extend across lower-level sensory physical and higher-level cognitive processes.

Differences in L1 and L2 Speech Processing

To address whether L2 speech engages specialized neural mechanisms, empirical research has investigated the nature of the differences between L1 and L2 speech processing. Initial research on the laterality effects of native and non-native speech compared the processing of Thai lexical tones by native Thai listeners and by English listeners whose L1 was nontonal (Van Lancker & Fromkin, 1973). The task was dichotic listening, in which two different tones were presented simultaneously, one to each ear. Since the right ear is primarily connected to the left hemisphere and the left ear to the right hemisphere through contralateral pathways, a right-ear advantage (indicating left-hemisphere dominance) was expected if tones were processed as linguistic stimuli. The results showed that only the native Thai listeners exhibited a significant left-hemisphere dominance. A follow-up study with musically trained English listeners revealed no hemispheric dominance for tone either, indicating that the left-hemisphere dominance found in the Thai listeners was due to their linguistic experience rather than greater familiarity with pitch contrasts. Consistently, research with Mandarin Chinese tone revealed that while Chinese listeners processed tone predominantly in the left hemisphere, Norwegian listeners exhibited bilateral processing, despite their experience with Norwegian tone (Wang, Behne, Jongman, & Sereno, 2004). Taken together, these studies suggest that left-hemisphere specialization for speech sounds occurs only when they are part of the listener's phonemic repertoire.

The behavioral differences for native and non-native speech processing have been revealed in neural-based studies. One widely used approach is to examine the event-related

brain potentials (ERP), by comparing the differences in the peak amplitude and latency of brain waves associated with the detection of differences in the stimuli. A particularly important ERP component in auditory speech processing is called mismatch negativity (MMN), consisting of a peak amplitude difference in the waveforms at around 150–200 ms post-stimulus onset upon detection of stimulus differences. Thus, the existence and magnitude of MMN may reflect the ability to distinguish speech sound contrasts. ERP studies have revealed that native and non-native speech processing may involve different sensory acoustic and linguistic levels, with native processing more susceptible to higher-level linguistic influence. For example, in the processing of Hindi stop consonants, an MMN was seen in Hindi but not English listeners, whereas the two groups did not differ in the ERP responses reflecting lower-level processing of acoustic signals (Sharma & Dorman, 2000). Similar processes have been shown with the processing of phonemic pitch contrasts versus within-category acoustic changes in pitch, where only the native group exhibited enhanced MMNs for phonemic differences, but response patterns to acoustic changes were the same for both native and non-native groups (Chandrasekaran, Krishnan, & Gandour, 2009b). Indeed, research has consistently revealed larger MMNs in response to the native speech contrasts than to those that are nonexistent in listeners' native phonetic inventories. These findings indicate that listeners are more sensitive to phonetic features in an L1 phonetic context, demonstrating experience-dependent neural effects in native and non-native speech processing.

Additionally, neuroimaging approaches (such as functional magnetic resonance imaging, fMRI) have been used to examine how the difference between native and non-native speech processing is localized in the brain. These techniques measure regional changes in blood flow in response to changes in neuronal activity, thus enabling localization of particular mental processes. Research has shown that the differences between native and non-native speech processing involve a network of brain regions, which go beyond the classic language areas in the left hemisphere such as Broca's and Wernicke's areas. For example, for lexical tone and vowel duration, native listeners revealed left-hemisphere activation in the pre-frontal, frontal (Broca's), temporal (Wernicke's), and parietal areas, while non-native listeners exhibited predominant right-hemisphere processing but a lesser degree of left-hemisphere involvement, even for those whose L1 was tonal. In contrast, for nonlinguistic pitch or duration patterns the native and non-native listeners exhibited similar patterns of bilateral processing in the frontal and parietal areas (Gandour et al., 2002). These findings agree with the behavioral and ERP results discussed above, indicating a language-specific top-down processing of pitch where non-native listeners' experience with acoustic cues may not be generated to higher-order linguistic processing. Moreover, the processing of different L2 linguistic speech features may involve different neural correlates depending on the nature of corresponding features in the L1. For example, while native tone-language users processed tone predominantly in the left-hemisphere temporal cortex, they processed intonation in the homologous right-hemisphere regions, presumably due to the greater linguistic functional use of tone than of intonation. In contrast, non-native listeners did not reveal any differences for the two tasks since tone was not used in their L1s (Fournier, Gussenhoven, Jensen, & Hagoort, 2010). Likewise, when processing prosodic focus and intonation, Chinese listeners showed different cortical patterns for L1 (Mandarin) and L2 (English) focus but not intonation, presumably because the phonetic manifestations of focus rather than intonation differ in the L1 and L2 (Gandour et al., 2007).

Thus, the behavioral and brain data consistently reveal that, compared to L1, L2 speech processing may involve delayed latency and weaker sensitivity, as well as different and additional cortical regions, with the nature of these differences being determined by L2 users' linguistic experience.

Experience- and Learning-Induced Plasticity

Given the differences between native and non-native speech processing, one subsequent question is the extent to which the human brain has the capacity to change with continuous L2 learning. Empirical research has shown that language-related cortical responses differ as a function of experience with an L2, depending on such factors as age of L2 acquisition (AOA), L2 proficiency, and exposure to and training in the L2.

First, age has been shown to affect hemispheric lateralization for L2 speech: Learners with an early AOA tend to involve more left-hemisphere processing than do late learners (e.g., Sussman, Franklin, & Simon, 1982). Moreover, ERP research has revealed changes in MMN patterns as a function of L2 proficiency, showing that advanced rather than naive Hungarian learners of Finnish approximated native Finnish MMN patterns for processing the Finnish vowel contrasts (Winkler et al., 1999). These findings indicate experience-induced cortical differences in L2 speech processing.

One widely used method to experimentally assess the plasticity of the brain in L2 speech learning is laboratory-based perceptual training. Initial behavioral studies have shown that, after about two weeks' training, adult L2 learners can significantly improve their perception of L2 speech contrasts, suggesting that the adult human perceptual system still has the capacity to change. Consistently, ERP results have demonstrated that training can enhance the MMN responses (particularly in the left hemisphere) to L2 speech contrasts (Zhang et al., 2009). Moreover, changes in neural sensitivity due to training may be differentially affected by listeners' L1. For example, after training with Thai tones, Chinese listeners (with a tonal L1), compared to English listeners (with a nontonal L1), exhibited a larger negativity at a delayed latency, indicating that tonal L1 users were more sensitive to linguistically relevant pitch differences (Kaan, Wayland, Bao, & Barkley, 2007). Training effects have also been exhibited in the spatial domain, showing that the cortical effects of learning an L2 involve both the expansion of preexisting language-related areas and the recruitment of additional cortical regions. After training with English /r-l/, Japanese learners' improvements were associated with extended bilateral cortical and subcortical regions involved with auditory-articulatory mappings related to speech processing (Callan et al., 2003). Likewise, for American learners of Mandarin tones, the cortical instantiation of training effects involved increased and expanded activation in Wernicke's and adjacent areas as well as the right-hemisphere regions homologous to Broca's area (Wang, Sereno, Jongman, & Hirsch, 2003). Moreover, training may result in a higher degree of neural efficiency, focusing on the areas involved in native processing (Golestani & Zatorre, 2004). Particularly, more successful learners have shown increased activation in the left-hemisphere regions associated with L1 linguistic processing, indicating an association between the degree of neural plasticity and language learning (Wong, Perrachione, & Parrish, 2007).

In sum, these patterns indicate progressive cortical changes with training and increased proficiency, suggesting that cortical representations may be continuously shaped with experience and learning.

Across Acoustic, Linguistic, and Cognitive Domains

While L2 speech processing apparently involves language-specific brain mechanisms, it is also a part of an interconnected neural system entailing integrated mechanisms across sensory-motor, linguistic, and general cognitive domains.

As discussed earlier, L2 speech processing may to a large extent overlap with the processing of acoustic information. For example, while native processing of fricative contrasts consistently elicited an MMN in the left hemisphere, non-native processing involved

a shift in MMN amplitude from the right hemisphere for the initial frication noise to the left hemisphere for the later fricative–vowel transition, reflecting non-native listeners' sensitivity to the acoustic differences of the stimuli (Lipski & Mathiak, 2007). Moreover, the weaker and later MMN responses in processing some L2 speech contrasts may have stemmed from the reduction of acoustic information available to L2 learners or to the difficult acoustic context that the neighboring sounds create (Frenck-Mestre, Meunier, Espesser, Daffner, & Holcomb, 2005). Additionally, listeners may seek alternative routes to process L2 speech by encoding the cortical regions used for articulatory-oro-sensory, primary auditory, and acoustic processing (Callan, Jones, Callan, & Akahane-Yamada, 2004).

As speech processing occurs concurrently with that of other linguistic domains, the processing of L2 phonetic information may uniquely interact with lexical, semantic, and prosodic processing. For example, while Spanish learners showed increased activation in the right-hemisphere regions for processing phonological information compared to semantic information in their L2 (English), the processing patterns for these two types of stimuli in their L1 did not differ, suggesting shared neural networks for L1 and L2 semantic processing but L2-specific phonological neural circuits (Pillai et al., 2003). Similarly, L1 and L2 phonological representations have been shown to differ in the mental lexicon: Spanish-dominant Spanish–Catalan bilinguals exhibited a larger phonological error-related ERP component in detecting words involving Catalan vowels, whereas they showed a larger semantic-related ERP component for words involving Spanish vowels (Sebastian-Galles, Rodriguez-Fornells, de Diego-Balaguer, & Diaz, 2006).

L2 speech processing may also involve cognitive processes such as memory, attention, and cognitive control. Greater attention and cognitive control have been claimed to be associated with additional activities in the prefrontal and anterior cingulate cortex. Likewise, better L2 attainment may be correlated with more optimal engagement of phonological working memory, indexed by greater activation in the left insula (Chee, Soon, Lee, & Pallier, 2004). Additionally, speech shares some neural mechanisms with music, given that pitch and temporal perception are fundamental to both. It is thus conceivable that music experience may facilitate speech learning. Indeed, for linguistic pitch (tone) processing in Mandarin, English musicians approximated the native Chinese patterns with larger MMNs than English non-musicians (Chandrasekaran, Krishnan, & Gandour, 2009a). Music experience has also been shown to facilitate the categorization of prosodic endings in an L2, as indexed by the earlier ERP responses for non-native learners with musical experience compared to non-musicians (Marques, Moreno, Castro, & Besson 2007). These findings imply that long-term experience in pitch across domains may result in cortical plasticity to pitch.

Conclusion and Future Directions

Taken together, empirical evidence cumulatively indicates that L2 speech processing involves experience-dependent but domain-general processes. On the one hand, the processing of L2 speech does encapsulate unique neural substrates under the influence of the L1 system. On the other hand, it does not just engage a single process or a single domain, but rather functions in the context of language processing in general, reflecting the integration of cortical networks across sensory-motor and cognitive levels. Moreover, L2 speech processing involves a dynamic process as a function of experience and learning. A convergence of data speaks against the maturation-based CPH, revealing neural plasticity involving changes in the temporal dynamics and cortical organizations of L2 representations in the brain.

Nevertheless, the nature of the CPH in L2 speech learning is still a matter of ongoing debate, as the brain data have only recently been systematically quantified with the advent

of neuroimaging techniques. It remains to be elucidated how cortical representations can be continuously shaped with learning. Future longitudinal studies tracing L2 speech learning trajectories are needed in order to define the agents of neural plasticity at various stages. Another direction for future research is to take into account individual differences. Although not yet extensively investigated, existing evidence indicates that the nature of individual processing patterns may trace the origin of speech processing as well as predicting learning success. All in all, L2 speech research addressing different stages of learning, different domains involved, and different factors affecting learning will lead us toward a complete picture in unraveling the neural mechanisms underlying L2 speech learning.

Second Language Vocabulary Attrition

LYNNE HANSEN

The forgetting of words is commonly experienced by learners of languages after the mother tongue. While loss of languages acquired in classrooms and in foreign and second language contexts has been a focus of research only recently (for an overview of this subfield of applied linguistics, second language attrition, see Bardovi-Harlig & Stringer, 2010), the loss of vocabulary has received greater attention than have other aspects of language, leading to interesting insights on factors which impede or promote lexical retention. While descriptive data-based studies have dominated this area of inquiry, theoretical frameworks suggest promising research directions for the future.

In language attrition research, second language (L2) lexical knowledge has been defined and investigated in various ways (for an early review see Weltens & Grendel, 1993). Thus, the variety of research methods and the complex nature of lexical knowledge need to be kept in mind in the interpretation and comparison of studies of vocabulary loss. For example, pioneering investigations of L2 vocabulary attrition in the Netherlands focused on the receptive knowledge of words, which has since been found to be more readily acquired and less prone to loss than productive knowledge. Although the attriters judged their lexical loss to have been considerable, little attrition was actually found in their receptive knowledge (Weltens, 1989). Thus, Weltens and Grendel (1993) suggested that future research should focus on the *production* of words. Subsequent studies have done so to a large extent as they investigated three main populations of language attriters: (a) college and high school students, (b) child returnees from residence abroad, and (c) returned LDS (Church of Jesus Christ of Latter-Day Saints) missionaries (Bardovi-Harlig & Stringer, 2010).

Linguistic and Extralinguistic Influences on Lexical Attrition

Evidence on the influence of language distance on lexical loss comes from paired-associate learning experiments. L2 cognate translations were learned and retained better than non-cognate translations by university students (Ellis & Beaton, 1993; De Groot & Keijzer, 2000). Thus, the assumption is that the more an L2 word resembles the corresponding word in the first language, the better it will be maintained. This idea is supported further in examinations of vocabulary attrition in natural contexts. For example, Weltens's (1989) study of the L2 French lexicon of Dutch students found high-frequency cognates were retained best while low-frequency non-cognates were most vulnerable to loss. In another adult population, LDS missionaries, the rates of both lexical learning and loss related significantly to the distance between the first language (L1) and the particular L2 learned (Hansen, 2011). Similarly, in a study of L2 English attrition and retention in university students two years after instruction ended, Xu (2010) found that Dutch learners (L1 related closely to English) maintained their vocabulary, while Chinese learners (L1 unrelated to English) experienced lexical attrition.

An early finding on word-length effects on retention was that longer words in L2 German were more difficult to learn and to retain than shorter words by L1 English university students (Ellis & Beaton, 1993). In a more unexpected finding in a study of L1 English missionaries who had learned German, Korean, or Chinese abroad, there was a significant

effect of the length of the corresponding L1 words on L2 lexical retention (Hansen, Kim, Lee, & Lo, 2010). While L2 word length did relate significantly to retention, the relationship with L1 length was even stronger. In a longitudinal study of returned missionaries, Hansen (2011) found that words relearned by returned missionaries in 2010 differed in length between words they had forgotten before 2000 and words they had forgotten between 2000 and 2010 (earlier forgotten words tended to be longer). The difference did not reach the level of significance for the length of the forgotten L2 words themselves but was significant for length of the corresponding words in L1 English.

Evidence on frequency effects on word retention comes from Dutch and German students returned from study abroad in Spain who named high-frequency Spanish words faster and more correctly than medium- and low-frequency words in a picture-naming task (Mehotcheva, 2010). In a study of returned missionaries, a word's vulnerability to loss related significantly to the number of occurrences per 1,000 in L1 English but not to the frequency of the target word itself in the second language (Hansen, 2011). While frequency affects L2 vocabulary *acquisition* in L2 contexts because it determines exposure (Ellis & Beaton, 1993), in L2 vocabulary *attrition* evidence from the missionary studies suggests that, at least in an L1 context, a word's vulnerability to loss may be affected to a greater extent by frequency of the corresponding word in the mother tongue than by the frequency of the word in the L2.

Although concrete words have been found easier to learn than abstract words (Ellis & Beaton, 1993; De Groot & Keijzer, 2000), several recent studies of the L2 English of Arabic- or Farsi-speaking adults in the Middle East failed to find significant differences between them in vocabulary attrition; nor did they find differences in susceptibility to loss between general versus technical terms (for a review, see Abbasian & Khajavi, 2010).

The importance of age in child lexical attrition has been substantiated in numerous studies which report that the younger the child, the more rapid the word loss (for a review, see Tomiyama, 2009). For example, Cohen's (1989) investigation of the loss of productive vocabulary in Portuguese as a third language of two English-Hebrew bilingual children, aged 9 and 13, found that, after nine months of discontinued contact, the younger subject exhibited greater lexical loss in storytelling than the elder. Yoshitomi (1999) argued that, although not immediately apparent, L2 attrition starts as soon as children return home from a stay abroad.

Although rapid attrition of unused vocabulary is the rule for young children, adults may experience more favorable outcomes, influenced by the extent of their initial vocabulary attainment. For example, in Mehotcheva's (2010) study of returnees from study abroad in Spain, initial Spanish proficiency was the most reliable factor in predicting results on picture-naming scores later on. Similarly, in Xu's (2010) study of the English attrition of Chinese and Dutch university students, one of the main findings was the strong effect of initial L2 proficiency on subsequent retention. For adults who attain relatively high levels of proficiency, such as Dutch students who learn French at school (Weltens, 1989) and LDS missionaries (Russell, 1999), an initial plateau of a few years is reported during which loss is slight. For the returned missionaries this is followed by a more accelerated decline over several decades, which increases in middle age (Hansen, 2011). Learners who attain lower levels of proficiency, however, follow a different attrition path from that of the advanced learners, as in a study of 773 former students of Spanish who experienced significant lexical attrition during the first three to six years following instruction (Bahrick, 1984). Subsequently their knowledge remained level for several decades, with an accelerated decline in middle age.

With regard to affective variables, Weltens and Grendel (1993, p. 146) suggested that learner attitudes and motivation in lexical attrition may have a relatively weaker effect

than in lexical acquisition. To investigate this idea, a research design incorporating several affective variables was used in studies of both missionary vocabulary acquisition (Hansen, Lam, et al., 2012) and returned missionary vocabulary attrition (Hansen, Chong, et al., 2012). The results suggest that, while language-learning motivation has a relatively strong effect in acquisition, it has only marginal significance in the retention of words after return to the English milieu. With regard to attitudes toward the second language and culture, although a positive trend in the relationship with vocabulary knowledge is discernable in the learner data (attitude toward language and culture related significantly to learners' vocabulary score), none is found for the returnees (attitude did not relate significantly to attriters' score). In addition, although belief in a spiritual component in language learning relates significantly to missionary vocabulary acquisition, after return we see no relationship between this belief and subsequent maintenance of mission lexicon. Thus, an overall comparison of acquisition and attrition data of the missionary population supports Weltens and Grendel's (1993) conception of affect playing a relatively minor role in L2 vocabulary loss. Similarly, in a study of the L2 vocabulary retention of Dutch and German students who had learned Spanish in Spain, Mehotcheva (2010) found no firm support for the role of attitude and motivation. Furthermore, in a study of the effects of attitudes toward L2 English on its attrition, Xu (2010) found a modest effect in the lexical attrition of Chinese university students, but none for Dutch students, as pointed out in the earlier discussion of the influence of the distance between the L1 and L2 on vocabulary retention.

In summary, salient linguistic influences on L2 word retention are the distance between the learner's L1 and the L2 (words in related languages are easier to remember), L2 word length (shorter words are easier to remember), and L2 word frequency (more frequent words are easier to remember). However, in L1 contexts of loss, at least, there is evidence that the length and frequency of the corresponding L1 word may have an even stronger influence on retention (if the corresponding word in the L1 is shorter/more frequent, the L2 word will be easier to remember). Extralinguistic influences affecting lexical retention are age (older children retain words better) and vocabulary size (learners who learn more words retain a larger proportion of the words known). Little evidence is found, however, for the influence of affective factors such as motivation and attitudes in L2 lexical attrition.

Theoretical Explanations Applied in L2 Vocabulary Attrition Studies

Hypothesis-driven investigations are in the minority in language-attrition research to date, with most of the studies predominantly empirical and exploratory in nature. Among the few theories applied in studies of lexical loss, the dormant-language hypothesis holds that, even at the end point of attrition, where conscious knowledge is lost, vestiges of the language endure in the mind. In L2 vocabulary attrition research, this idea surfaces in relearning studies motivated by the savings paradigm from cognitive psychology. The savings approach is based on the premise that, for previously known words that can no longer be recalled or recognized, knowledge remains that can be activated in relearning. The hypothesis receives support in studies of the L2 vocabulary of children who had forgotten words learned abroad (Tomiyama, 2001), of adults who had forgotten words learned in childhood (De Bot & Stoessel, 2000), and of adults who had forgotten words learned as adults during residence abroad (Hansen, 2011).

The oldest theory applied in vocabulary attrition research is the regression hypothesis, which predicts that the path of attrition will be the reverse of the path of acquisition (for a review, see De Bot & Weltens, 1991). In a 12-year longitudinal study of the retention of Japanese particles by returned missionaries, Russell (1999) reported that the particles

acquired most recently tended to be lost first, as predicted by regression theory. In cross-sectional missionary studies, having established rank-order scores for missionary vocabulary learning in each of six languages (Chinese, German, Japanese, Korean, Portuguese, and Spanish), Hansen (2011) found that words with higher rank order in the learning period tended also to have an advantage in the retention of these languages over 50 years. Similarly, in a study of the acquisition and attrition of Chinese and Japanese numeral classifiers by missionaries, accuracy comparisons between learners and attriters indicated that the counter words which are most accessible in learning tend to be retained longest, and those which are less accessible in learning are more susceptible to loss (Hansen & Chen, 2001).

Hansen and Chen (2001) also examined their Chinese and Japanese numeral classifier data in light of markedness theory. In L2 acquisition theory, hierarchies of markedness impose paths of least resistance (acquisition orders) in language learning. For classifiers, research on their occurrence and development in many languages has established an implicational scale of markedness which tended to be adhered to by the adult learners and attriters in both their learning and loss of counter words. That is, the least marked classifiers tended to appear earlier and to be retained longer.

Conclusion

There has been progress in our understanding of lexical attrition since Weltens and Grendel's (1993) conclusion that the effects of such variables as proficiency level, language distance, and attitude were unclear. While we have seen clarification of the influences of these and other factors in vocabulary loss since the early 1990s, still we are left with a shortage of theoretical explanations for the phenomenon. Furthermore, current trends in science are away from models which are based on linear and hierarchical assumptions such as those of markedness and regression theory.

The applications of the savings paradigm in vocabulary relearning studies attest to the continuing presence in memory of "forgotten" words. What appears to happen in the course of language attrition is a general reduction in the availability of lexical information. Through disuse, the language attriter may initially take longer to retrieve lexical elements. Over time the search for stored knowledge may increase in length and difficulty until the final stage of L2 vocabulary attrition when words are entirely inaccessible or, as we say, "forgotten."

A criticism of the previous approaches for explaining lexical attrition has been the failure to recognize the systematic and dynamic nature of vocabulary knowledge. In remedying this weakness, dynamic systems theory (DST) is suggested as a promising candidate to be used in accounting for language and language development (De Bot, Lowie, & Verspoor, 2005). However, the theory is challenging due to the complexity of interacting factors in the systems and lack of clarity about the methodology which could be applied. Another suggestion comes from Meara (2004) who states that real strides in theorizing about the L2 lexicon will occur only when vocabulary researchers take on board the radically new ways of looking at vocabulary that are emerging on the edges of computational linguistics. However, the potential interest in these ideas lies largely in experiments that have not yet been conducted.

Second Language Word Difficulty

BATIA LAUFER

To understand why some words are easy and some are difficult for second language learners, we should first clarify what is meant by knowing a word. Word knowledge can be defined as the information about a word which is stored and interconnected in our mind. This knowledge has typically been described as consisting of a range of aspects of knowledge including knowledge of spoken and written form, morphological knowledge, knowledge of word meanings, knowledge of the word's grammatical features, knowledge of how the word is related to other words in the language (i.e., paradigmatic and syntagmatic associations), and knowledge of constraints to be observed in the use of the word (Richards, 1976; Nation, 2001). Thus, knowing a word has been seen to involve a variety of different kinds of interrelated "subknowledges." The term "word" includes multiword units which form one unit of meaning. Thus *of course*, *as a matter of fact*, *put off*, and *sit on the fence* are treated as words and the features of difficulty discussed here are relevant to single words and to multiword units.

A word can be known receptively or productively. Receptive knowledge is associated with listening and reading and implies that we are able to comprehend the input and are able to perceive the form of the word and retrieve its meaning or meanings. Productive knowledge is associated with speaking and writing and implies that we can retrieve the appropriate spoken or written word form of the meaning that we want to express. Ideally, knowing a word means mastering all the "subknowledges," both receptively and productively. In practice, however, each of these "subknowledges," or features, can be mastered to various degrees by a second language (L2) user.

We will now look at separate features of knowledge in terms of potential learning difficulties they may induce. We will notice that some of these difficulties are related to the word itself, others to the interaction between the word and other words familiar to the learners either in their first language (L1) or in the language they are learning. As our concern here is the intrinsic difficulty of words, we will not discuss other factors outside the word and the lexicon, which may affect learning difficulties, such as teaching techniques, learner motivation, word frequency in the input, and so forth. Nor will we discuss non-objective word features such as meaningfulness and imageability. A word can evoke a different number of images and have differential meaningfulness to different people. Similarly, we will not discuss abstractness, which is related to the degree of imageability, which, in turn, can be user-related.

Spoken Form: Pronounceability

The difficulty of an L2 word may depend on how easily it is pronounceable in terms of its individual phonemes, their combinations, or suprasegmental features (stress, tone, intonation). The difficulty of pronunciation is largely determined by the learner's L1 phonological system. The L1 system may be responsible for the learner's inability to discriminate between some phonemes and subsequent confusion of words differing in these problematic phonemes. Examples of problematic pairs of words for learners of English are: *ban/van* for Spanish speakers; *live/leave*, *bad/bed*, and *think/sink* for speakers of Hebrew;

2 SECOND LANGUAGE WORD DIFFICULTY

six/sex for speakers of Arabic. Similarly, the initial consonants or clusters in *just*, *shop*, and *strange* may be hard for Spanish speakers, while the final clusters in *clothes* and *film* are hard for speakers of Hebrew. The variability of English stress (*photograph*, *photography*, and *photographic*) with subsequent weakening of vowels in the unstressed syllable may also affect the difficulty of word pronunciation.

Written Form: Spelling

The degree of sound–script correspondence in a word can be a facilitating, or difficulty-inducing factor. Learners of Italian will know how to pronounce a new word they see in a text. So will learners of French, provided they know which letter combinations represent which sounds (e.g., *eau* /o/) and that final consonants are not pronounced (e.g., *printemps*). In English, however, the written form of a word may provide no clues to its pronunciation, for example, the letter *o* is pronounced differently in *love*, *chose*, *women*, and *odd*. Words with incongruence between the sound and the script are good candidates for mispronunciations and spelling errors. A different writing system in L1 can also account for some difficulties in the recognition and production of written words. Native speakers of Semitic languages, which do not represent all the vowels in script, tend to be “blind” to vowels in English and confuse written words with identical or almost identical consonants *pulls/pulse*, *decimal/dismal*, *available/valuable*, and *embrace/embarass*.

Word Form: Morphological Structure

Some inflectional features that can affect word difficulty are irregularities of plural, gender of inanimate nouns, and noun cases. Among derivational features of difficulty are irregularities in the combination of morphemes (e.g., *over* in *overfly* means ‘on the top/across’, but in *overthrow* it can mean ‘put an end to’ and in *overcook* ‘too much’) and deceptive transparency (Laufer, 1989). Deceptively transparent words look as if they were combined of meaningful morphemes, though they cannot be broken into morphemes, for example, *shortcomings* was interpreted by students as ‘short visits’ (*short* + *comings*), *discourse* as ‘in the wrong direction’, *infallible* as ‘something that cannot fall down’, and *outgrow* as ‘grow outside’.

Synformy: Similarity of Lexical Forms

Studies of lexical errors in writing, association tests, and tests that elicited distinctions between words showed that learners tend to confuse words that are similar in sound, script, or morphology (Laufer-Dvorkin, 1991; Fitzpatrick, 2006). Similar lexical forms were called “synforms” by Laufer. She identified 10 categories of synforms, each category representing a different pattern of similarity. Some examples of synforms are: *adapt/adopt*, *conceal/cancel/counsel*, *embrace/embarass*, *cute/acute*, *lunch/launch*, *industrious/industrial*, *exhausted/exhaustive*, *economic/economical*, *sensible/sensitive/sensual*.

Grammatical Properties of a Word

Most problems with grammatical properties of the word result from L1–L2 difference. For example, if a prepositional verb in one language is nonprepositional in another language, or a count noun in one language is noncount in another, learners tend to transfer the L1 grammatical properties. Hebrew L1 speakers drop the preposition in *operate on*, but add

a preposition to *enjoy* and say **enjoy from*. They also assign the plural form to some non-count nouns **advices*, **evidences*. Word class and length are sometimes claimed to affect word difficulty. However, it is not clear that these features can be properly isolated from other word properties. For example, long words can be combined of familiar morphemes, as in *unavoidable*, and this familiarity facilitates learning.

Meaning

The most important property of word knowledge is the ability to connect word form to its meaning, or meanings for those words that have several meanings. Semantic knowledge also entails the awareness of boundaries between semantically similar words, for example, *wastebasket* and *rubbish bin*, *walk* and *stroll*. Languages share lexical common ground resulting from universality of human experience. Without such common ground, it is questionable whether teaching and learning foreign vocabulary would be possible. Yet different languages classify some areas of experience in different ways by means of words. When the foreign language and the learner's mother tongue classify an area of experience in the same way, that is, attach a different "label" to a similar concept, the only learning task is to remember a new word for a familiar referent, for example, English and French *write* and *écrire*, *computer* and *ordinateur*. However, in many cases, the "parallel" concepts in the two languages do not overlap. For example, both *house* and *home* are expressed by the same word in French *maison*. Similarly, *evaluate*, *appreciate*, and *estimate* are translated in Hebrew as *leha'arich*. The semantic boundaries between *cup* and *glass* are not the same as between *kos* and *sefel* in Hebrew. Though a *glass* cannot be made of plastic and a *cup* can, both *kos* and *sefel* can be made either of plastic, paper, or glass. A particular word in one language may cover only part of the uses of its translation "equivalent" in another language, and each of the words has other uses of its own. For example, *go* can be translated into Hebrew as *halach* in *He goes to a good school*. But *go* is translated into *nasa* when the action involves some kind of transport as in *He went from London to Paris*. But *nasa* can also mean *travel* and *halach* can mean *walk*. *Walk*, however, can be translated as *tijel* when an element of leisure is involved. Lack of word-for-word overlap between L1 and L2 meanings is also the most important factor in collocation (word combination) difficulty (Nesselhauf, 2005), as will be mentioned later. For example, *follow instructions* is translated by *obey instructions* in Hebrew. Lack of one-to-one overlap in the lexical coverage of a concept is a source of learning difficulty. In addition to traditional error analysis studies which showed that this was one of the major L2 lexical difficulties (Duškova, 1969; Ringbom, 1982), some recent psycholinguistic studies lend support to the same conclusion and show that even advanced L2 learners map English words onto the L1 concepts (Jiang, 2004).

Languages can be different in the figurative meaning of a word or word phrase even though their literal meaning may be similar. So the literal meanings of *red tape* and *miss the boat* is identical in English and Hebrew. However, there is no idiom in Hebrew which means *red tape* in the sense *bureaucracy* and the figurative expression for 'miss an opportunity' is 'miss the train'. Laufer (2000) found that some types of idioms are avoided in L2 production even when learners are familiar with them, particularly idioms that do not exist in the L1 or are partially similar to the L1, as in the two examples above. Yet idiomaticity seems to present a difficulty even when the L1 and the L2 are similar in the idioms. Kellerman (1986) found that Dutch learners of English assumed that some idioms with the words *break* and *eye* would not transfer to English even though they were identical in the two languages. Grant and Bauer (2004) distinguish between figuratives and core idioms. Figuratives are expressions where with some effort a relationship can be seen between the parts and the whole, as in *give the green light* and *just what the doctor ordered*. Core idioms

4 SECOND LANGUAGE WORD DIFFICULTY

are expressions where the meaning of the parts does not provide access to the meaning of the whole, as in *by and large* and *out of hand*. They constitute a much smaller group, yet they are very difficult to learn.

An extreme case of lack of semantic overlap is a lexical void, which means that an L2 word has no translation in the L1 due to nonexistence of a concept denoted by the L2. Spanish does not seem to have exact equivalents for *fussy*, *fidget*, and *grudge*; Hebrew has no equivalent for *cozy*, *quaint*, or *in-laws*. Learning a word which is a void in L1 is a difficult task since a new concept has to be created together with a word to represent it.

Language learning would be easier if one form were associated with one meaning. In practice, one word form could represent several meanings (e.g., *bank*, *subject*, *lie*), or one meaning could be represented by different word form (e.g., *lift/elevator*, *meet/encounter*).

Learners who came across such words in a text and were familiar with one meaning only did not abandon it even though it did not make much sense in context (Bensoussan & Laufer, 1984). For example, *since* (because) was interpreted as *from the time when*, and *course* (duration) as *part of a meal*. In production, learners may prefer words without multiple meaning, for example, *The Labor party was in power* rather than *The Labor party was in office*.

Form and Meaning vis-à-vis L1

Many words in a newly learned language may be similar in their form to the word form in learners' L1 since some languages are historically related (e.g., English and French) and even languages unrelated genetically borrow words from other languages. Thus a French-speaking learner of English will have no problem learning *liberty*, *simple*, and *educate* because they are similar to *liberté*, *simple*, and *éduquer*. These words are called "cognates" in languages that are related historically, and "borrowed words" in unrelated languages. However, sometimes though the form is similar in two languages, the meaning is not. In French, *actuel* means 'topical', not 'actual', *sympatique* means 'nice', not 'sympathetic'. Words that are similar in form but different in meaning are called "false friends." In learning these words, learners have to dissociate a familiar form from a familiar meaning and acquire a different one.

Register

Learners are often unaware of the fact that lexical items that are frequent in one mode of discourse may sound strange in another, or that words that are acceptable when used with some interlocutors may be out of place with others. For example, *the lesson commences at 9 a.m.* sounds strange in spoken language. A teacher would not suggest to a parent that she take her child to a *shrink*.

Word Combinations: Collocations

Collocations are habitually occurring lexical combinations that are characterized by restricted co-occurrence of elements and relative transparency of meaning, for example, *submit an application*, *heavy traffic*, and *follow instructions*. Since many collocations are comprehensible if the learner is familiar with the individual words, the difficulties occur in language production. Some collocations are overused by learners, by comparison with native speakers, for example, collocations constructed with core verbs (*be*, *have*, *make*, etc.), while other native-like collocations are not used at all (Cobb, 2003). Errors are abundant in the performance of learners, including in the language of advanced college learners, particularly when collocations differ in L1 and L2 (Nesselhauf, 2005; Laufer & Waldman, 2011).

Conclusion

The discussion above shows that word difficulty implies mastering patterns of knowledge that learners are unfamiliar with. For example, words that refer to concepts familiar from L1 are easier than words that denote concepts nonexistent in L1; a word with several meanings is more difficult than a word with one meaning. It also follows from the discussion that active or productive knowledge is more difficult to achieve than passive or receptive knowledge because there is more to learn about a word in order to use it correctly (except in the case of borrowed words). Comprehending a word requires the knowledge of its meaning. The other features of the word are provided by the text writer or speaker. Using a word, on the other hand, requires the knowledge of its pronunciation, or spelling, collocations, grammatical features, and register.

Segments

ROBERT S. CARLISLE

What Is a Segment?

Oral language is a system of communication that relates sound to meaning. Speakers of languages know that the meanings of words are different from one another because words are composed of different sequences of sounds. Native speakers of English, for example, will correctly state that *frog* has four sounds, revealing an ability to perform a rudimentary segmental analysis to identify the sound segments, also known as phones, found in human language. Though identifying the segments in words seems like a simple task, it is actually quite remarkable because any analysis of the physical record of the stream of speech displays that speech is a continuous property that does not readily reveal even the boundaries of words let alone the boundaries of individual sounds. Nevertheless, speakers can identify individual sound segments, and the assumption that words can be divided into discrete sounds, the absolute slicing hypothesis (Goldsmith, 1976), has been a necessary condition for the development of the International Phonetic Alphabet and modern phonology (see Odden, 2005, as an example). Further evidence for the existence of discrete sounds comes from the ability of speakers to manipulate them both consciously and unconsciously. When people play oral language games such as pig Latin, they consciously manipulate individual sounds by first moving one; if a word begins with a consonant, they move it to word-final position. Next, they insert a long *a* sound (here denoted as *ay*) to the end of the moved consonant. So a phrase such as *big bad beast* is rendered as *igbay adbay eastbay*. Speakers also unconsciously move sounds. Slips of the tongue reveal that speakers can transmute two sounds from two different syllables or words provided that they occur in the same position in both sources. Famous examples of this transmutation come from spoonerisms such as the uttering of *the queer old dean* for the intended *the dear old queen*. Speakers could only make such errors if sounds were discrete and independent. Further evidence for the manipulation of discrete sounds is that speakers of any language can produce sounds in isolation. If asked to produce the sound of *s*, speakers will, nearly without exception, produce an *s* sound. One last piece of evidence is that if speakers are given an environment such as *__at* and asked to create words by inserting one sound, they can produce an inventory of words such as *cat*, *fat*, *mat*, and *rat*.

Phoneticians and phonologists cannot pinpoint the exact number of segments in language, but Ladefoged (2005) estimates that the world's languages contain about 600 consonants and 200 vowels. Some of these segments are so similar, however, they could not occur in the same language to signal differences in meaning; that is, they are not contrastive in the same language. For example, English and Russian have a *p* sound, both of which are bilabial; nevertheless, the two differ in articulation. Whereas English speakers merely bring their lips together to form the sound, Russian speakers draw their lips slightly inward before putting their lips together, so although the two differ in articulation and count as two segments in the world's languages, acoustically, the two sounds are so similar no language uses both to contrast meaning.

Phonemes and Allophones

A change in sound can result in a change in meaning, a point easily verified with a minimal pair test. A minimal pair consists of two words that differ by only one sound occurring in the same position in both words; for example, the words *far* and *tar* form a minimal pair because *f* and *t* contrast in the same environment, *_ar*. Sounds contrasting in the same environment are known as phonemes. Phonemes, however, are not actually individual sound segments in themselves; rather they are cognitive abstractions physically represented by a number of phonetically similar segments that speakers classify in the same phonemic category. Take the phoneme /k/ in English as an example. (Phonemes are encased in slashes, also called virgules.) This phoneme is realized by a number of phonetically similar sound segments known as allophones. These different allophones differ on two features and different combinations of those features. The first feature is place of articulation; /k/ is normally a velar sound as in *cool*; that is, the back of the tongue rises up and touches the velum. However, when /k/ is pronounced before a non-low front vowel as in *key*, the body of the tongue moves further forward and touches the palatal region; in other words, the /k/ becomes palatalized, which readers can prove to themselves by uttering the words *cool* and *key* back to back a number of times. The second feature distinguishing the different allophones of /k/ is aspiration, an audible puff of air occurring between the release of the sound and the beginning of the vibration of the vocal cords that is a feature of the following sound. The aspirated allophones of /k/ occur in syllable-initial position before stressed vowels. As concrete examples of how these features configure differently, the *k* allophone in *cat* is aspirated, but not palatalized; the one in *kin* is aspirated and palatalized; the one in *skin* is palatalized but not aspirated; and the one in *scone* is neither aspirated nor palatalized. As just exemplified, different allophones of the same phoneme have different configurations of features, and where the different combinations of features occur depends upon phonological environment. The ability of native speakers to produce the appropriate allophone in any particular environment contributes to the speakers' accent. If a native speaker of English were to substitute an unaspirated *k* allophone in *kiss* for the normally aspirated allophone, he or she would not change the meaning of the word because allophones of the same phoneme do not contrast, but the person would no longer sound like a native speaker.

Segments and Features

Segments are not indivisible, being composed of subsegmental properties known as features. Among other properties, features identify the place of articulation of a segment (where in the oral cavity a sound is produced), whether it is voiced or voiceless, whether it is a vowel or consonant, whether it is oral or nasal, and whether it is a continuant (a sound that can be lengthened, such as *s*) or a noncontinuant (a sound that cannot be lengthened, such as *t*). For example, the segment [s] is composed of the following features: [+consonantal], [–sonorant], [–syllabic], [–nasal], [+continuant], [+anterior], and [+strident]. Each segment in a language is composed of a unique set of features, known as a feature matrix. However, the importance of features is not only to uniquely describe how each segment is produced, but to identify natural classes, groups of sounds that share one or more features and function as a group.

The members of a natural class function as a group in two ways. First, phonological processes apply to the sounds comprising a natural class. For example, vowels in American English are nasalized before nasals; that is, vowels acquire the feature of [+nasal] as in *bone* but not in *boat*. Second, natural classes frequently comprise the phonological environment in which a process takes place. As mentioned above, the natural class of vowels becomes nasalized only before the natural class of nasals. The production of a unique

segment in a given phonological environment displays the fact that speakers configure the phonetic features of segments in different environments; thus vowels which normally lack the feature of [+nasal] in their feature matrix acquire that feature only before nasals.

Segments in Second Language Acquisition

One great task facing second language (L2) learners is to configure features to produce the appropriate segments in given environments in the L2. The difficulty of this task is revealed in the great variability displayed in interlanguage segmental phonology; L2 speakers generally use a number of segments for any target segment in the L2. Some of these segmental variants come from the transference of sounds from the first language (L1); others appear novel and completely unpredictable. In addition, the production of segmental variants is greatly constrained by language universals.

Variation

In the 1960s a few sociolinguists began applying quantitative methodologies to analyze dialects, a procedure known as variation analysis (e.g. Labov, 1966, 1969; Wolfram, 1969). In the mid-1970s researchers began applying variation analysis to the study of interlanguage phonology, finding that L2 phonological production is also characterized by variability; L2 speakers use a number of variants for any L2 target segment, and the frequency with which the segmental variants occur is influenced by phonological environment. Variation is so common in L2 phonological production that Major (2001) has asserted that “any model, theory, or purported explanation that fails to account for variation is not accounting for the data, period” (p. 60).

Among the first to apply variation analysis to L2 acquisition were Lonna and Wayne Dickerson. L. Dickerson (1975) examined the production of (z) in English by native Japanese speakers. (Variables are encased in parentheses.) The variable had five variants with four environments conditioning the frequency with which the variants occurred. The target variant, [z], occurred most frequently before a vowel, less frequently before silence, and least frequently before consonants. In a second study with native Japanese speakers learning English, W. Dickerson (1976) examined the production of (l) in prevocalic position. The variable had five variants, conditioned by two sets of interacting constraints, one set before the variable and one set after. The target variant [l] occurred most frequently after silence, less frequently after a vowel, and least frequently after a consonant. The height of the vowel following the variable also influenced the frequency of the target variant, its presence being most frequent before a low vowel and least frequent after a high vowel. These two constraints interacted so that the target variant occurred most frequently in word-initial position before a low vowel, as in *lap*, and least frequently as the second member of a biliteral onset before a high vowel, as in *sleep*. (An onset consists of all consonants before a vowel in the same syllable, so the *sl* in *sleep* is a biliteral onset.)

In their third study with Japanese speakers learning English, Dickerson and Dickerson (1977) examined (r) in prevocalic position, finding that the occurrence of the target variant [r] also depended on the height of the following vowel: The lower the vowel, the higher the frequency of the target variant. In another early study, Gatlinton (1978) examined the production of the voiced *th* sound—(ð)—in English by French speakers and found that the occurrence of the four variants was conditioned by five preceding environments within and across word boundaries, the target variant [ð] occurring more frequently after a vowel than after any of the four consonantal environments.

Later studies relying on sophisticated statistical procedures revealed which phonological environments best induced the presence of target variants. For example, Rau, Chang, and

Tarone (2009) examined the production of the voiceless *th*—/θ/—in English by native Chinese speakers. As in previous studies, the researchers found that the L2 learners produced a number of variants including the target variant [θ]. Using a VARBUL analysis, the researchers were able to rank the environments and even combinations of environments that favor and disfavor the presence of the target variant. The L2 speakers produced a higher frequency of the variant in an onset, *thin*, than in a coda, *with*. (A coda consists of all the consonants after a vowel in the same syllable.) They also produced the target variant more frequently both in onsets and in codas when it was the only member, so the target variant appeared more frequently in words such as *thin* and *with* than in *three* and *fourth*. Finally, the target variant appeared more frequently in both onsets and codas when the vowel of the syllable was simple rather than a diphthong; consequently, the target variant appeared more frequently in words such as *thank* and *math* than in *thousand* and *mouth*.

Transfer

Transfer is a vital process in the structuring of interlanguage segmental phonology; learners readily transfer L1 segments into the L2. Positive transfer occurs when an L1 segment substitutes for a phonetically similar segment in the L2. For example, in Spanish the sound *n* is normally dental whereas the *n* in English is alveolar. Speakers of either language learning the other will tend to transfer the L1 segment into the L2 without hindering communication. Negative transfer of segments occurs when the substitution results in difficulties in communication. Spanish does not have a high back rounded lax vowel as in the English words *would* and *stood*, and Spanish speakers first learning English tend to transfer their high back tense vowel, with the consequence that *a good look* sounds like *a gude luke*.

Early adherents of contrastive analysis, such as Lado (1957), claimed that sounds that are similar across the L1 and L2 would be easy to learn, and those that are different would be difficult. However, this claim has been challenged by researchers such as Flege (1995), who proposed that the similarities between two languages rather than their differences cause the greatest problems in the authentic production of L2 segments. This is because L2 learners may perceive an L1 sound as equivalent to one in the L2 even though they differ on some features. Once L2 learners regard two sounds as equivalent, they may not make further effort to reconfigure the necessary features to make the L2 sound more native-like. For example, both French and English have voiceless stops: *p*, *t*, and *k*. In French these sounds are never aspirated. In English, however, the stops are aspirated in syllable-initial position before a stressed vowel. When English speakers learn French, they must learn to suppress aspiration. However, English speakers apparently regard their aspirated segments as equivalent to the French unaspirated segments and tend to produce segments with more aspiration than the French norm even after considerable experience with the L2 (Flege, 1987).

In contrast, some segments that are entirely nonexistent in the L1 may be relatively easy for learners. Flege (1987) examined the production of the French high front rounded vowel as in *tu* and found that English speakers had little difficulty producing it even though it is nonexistent in English. Also, Japanese speakers were able to successfully acquire the trilled *r* in Russian (Larson-Hall, 2004) though they apparently have much more difficulty acquiring the non-trilled *r* in English, supporting Archibald's claim (2009) that L2 learners may be able to acquire new sounds if they consist of salient phonetic cues. Archibald also asserts that some L2 sounds may be relatively easy to acquire if L2 learners can reconfigure features already present in the L1. However, as previously discussed, even though English speakers can produce unaspirated voiceless stops, they have difficulty suppressing aspiration when required to produce them in syllable-initial position in languages such as Spanish and French.

Though much evidence exists for transfer being an important process structuring inter-language phonology, research has also revealed that L2 learners produce segments in the L2 not found in either the L1 or the L2. For example, Nemser (1971) found that Hungarians learning English sometimes substituted *sth* for [θ], a sound occurring neither in English nor in Hungarian. In addition, Major (1986) found that Spanish speakers learning English produced an *r* sound not evident natively in either language.

Language Universals

A strong version of the contrastive analysis hypothesis asserted that researchers should be able to predict which sounds L2 learners would transfer, but a lot of research evidence weighs against this claim. For example, speakers of European French and Quebec French learning English substitute different sounds for the voiceless *th*, the former generally substituting [s] and the latter [t] even though they speak the same native language (Brannen, 2002; Lombardi, 2003). Further evidence against predictability comes from the variability found in the production of L2 segments previously discussed.

Eckman (1977) increased the ability of researchers to predict which segments would be easier to acquire by supplementing contrastive analysis with the notion of markedness as revealed through implicational relationships. Two structures are in an implicational relationship if the presence of one implies the presence of the other. The implied structure is marked (less preferred universally) relative to the other structure (see Greenberg, 1965, for examples). One example of markedness is the relationship between voiced and voiceless obstruents in word-final position. (Obstruents are consonants produced by two articulators actually touching or coming very close together; examples of voiceless obstruents include *p*, *t*, *k*, *f*, and *s*.) Many languages, such as Basque, German, Finnish, and Russian, allow only voiceless obstruents in word-final position. Other languages, such as English, allow a voicing contrast in word-final position, but no languages allow only voiced obstruents in word-final position, revealing that voiceless obstruents are less marked than voiced obstruents in that position. Flege and Dravidian (1984) examined the production of word-final voiced stops in English by native speakers of Spanish, Mandarin, and Polish. Spanish allows only a small number of continuants in word-final position; Mandarin allows only sonorants; and Polish allows both sonorants and obstruents, but the obstruents are devoiced. Because Polish speakers devoice obstruents in word-final position, the expectation was that Polish speakers would devoice more frequently than would the speakers of the other two languages. However, given that voiceless obstruents are less marked than voiced obstruents, speakers of all three languages should devoice some voiced obstruents in word-final position. The results supported the prediction: Polish speakers devoiced 48.3% of the final voiced stops; Spanish speakers 43%; and Mandarin speakers 29.5%, revealing that even speakers of languages that do not have either voiced or voiceless stops in word-final position will frequently produce the less marked variant.

The role of language universals is especially evident in the insertion of segments. L2 learners variably insert an unstressed vowel to modify onsets and codas disallowed by the syllable structure conditions of the L1. For example, neither Spanish nor Portuguese allows onsets consisting of [s] followed by another consonant. When native speakers of these two languages attempt to learn languages such as English or Swedish, which allow sC onsets, they tend to insert a vowel before the onset, thus forming a new syllable beginning with the vowel. The frequency of this vowel insertion (known as prothesis) depends upon the structure of the onsets because they are in implicational relationships, some being more preferred universally than others. The length of the onset is a factor; languages having sCC onsets as in *spleen* also have sC onsets as in *spoon*. Research has clearly demonstrated that L2 learners will more frequently use prothesis before the longer onset than before the shorter (Carlisle, 1997). Even sC onsets of the same length are in implicational relationships, so onsets consisting of [s] followed by an obstruent are more marked than

those consisting of [s] following by a nasal, which in turn are more marked than those consisting of [s] following by a liquid, /l/ or /r/. Again, research has revealed that these implicational relationships influence the frequency of prothesis. L2 learners use prothesis most frequently before words such as *stop*, less frequently before words such as *snow*, and least frequently before words such as *slow* (Carlisle, 2006).

Just as prothesis is a prevalent strategy for modifying onsets, deletion is a prominent strategy for modifying codas, and again syllable structure universals influence the frequency of deletion. Universally, longer codas imply the presence of shorter codas. If a language, such as English, has trilateral codas as in *forced*, it will have biliteral codas as in *lost*, and singleton codas as in *lot*. Research in L2 acquisition has revealed that the frequency of deletion correlates with the length of the coda. Weinberger (1987) examined the production of word-final codas by four adult speakers of Mandarin and found that they modified 5.5% of the singleton codas, 29.8% of the biliteral codas, and 42% of the trilateral codas. Anderson (1987) examined the production of English codas by native speakers of Egyptian Arabic and of Amoy and Mandarin Chinese. The native Arab speakers modified 2% of the singleton codas, 17.4% of the biliteral codas, and over 30% of the trilateral codas. The Chinese speakers modified 20% of the singleton codas, 50% of the biliteral codas, and 74% of the trilateral codas. For both groups, increases in the length produced significant increases in the frequency of modification.

Interlanguage phonology is a complex system characterized by inherent variability, and even though researchers have evidence for important processes such as transfer and the moderating influences of language universals in the structuring of the system, they are just as far from accounting for the formation of interlanguage phonology as they are from accounting for the formation of interlanguage syntax (Archibald & Young-Scholten, 2003).

Sejong the Great and the Creation of Hankul

JAE JUNG SONG

Sejong the Great (1397–1450) is regarded as the inventor of Hankul, arguably the most scientific and systematic writing system in the world. Sejong's writing system was devised on the basis of his understanding of the sound system of Korean, the equivalent of which can be found in some of the fundamental principles of modern phonology. The name of the writing system was initially Enmwun (meaning 'vulgar writing') but was changed in 1912 to Hankul (originally meaning 'great writing' but now generally understood to mean 'Korean writing').

Sejong, the third son of King Taejong of the Yi Choson Dynasty (1392–1910), ascended the throne in 1418 as the dynasty's fourth king at the age of 22. He was an unusual king in the sense that he was not only a monarch but also an exceptional scholar. Sejong's achievements during his reign (1418–50) are well documented not only in military expeditions but also in other areas, including agriculture, arts, law, music, medicine, science, and technology (see Kim-Renaud, 1992). The world's first udometer was invented under his auspices in 1442, almost two hundred years earlier than a similar device appeared in the West. In 1420, he established Ciphycencen ("The Academy of Worthies"), where he fostered a wide range of literary and other scholarly activities, including the "testing" of Hankul.

Unlike most monarchs that the world has known, Sejong was most benevolent. His philanthropic attitude toward his people was epitomized by his invention of Hankul. Having no script of their own, Koreans had had to draw upon characters imported from China. Although there had been a few attempts to adapt Chinese characters (as the Japanese had done with their Hiragana and Katakana systems), the dominant writing system in Korea, until the end of the 19th century, was Chinese. Only the powerful and educated (i.e., the ruling class) were able to learn and use Chinese characters; the masses had no access to writing of any kind. Sejong, educated in Chinese writing and classics, was so concerned about the absence of a writing system for ordinary Koreans that he decided to invent one. The documents explaining his own justification of Hankul and the exposition of the writing system have survived. The king made a remarkable statement in the preface to *Hwunminjeongeum* ("The Correct Sounds for the Instruction of the People," October 9, 1446):

The [sounds] of our country's language are different from those of the Middle Kingdom [China] and are not confluent with [the sounds of Chinese] characters. Therefore, among the [ignorant] people, there have been many who, having something to put into words, have in the end been unable to express their feelings. I have been distressed because of this, and have newly designed twenty eight letters, which I wish to have everyone practice at their ease and make convenient for their daily use. (translation from Ledyard, 1966)

Not surprisingly, the ruling class held on to Chinese characters even during Sejong's reign. Chinese was an emblem of their high social status. Monarchs who contemplated any departure from the norms of the ruling class would be seen to jeopardize the very

Table 1 Hankul: the basic set

<i>Vowels</i>										
ㅏ	ㅑ	ㅓ	ㅕ	ㅗ	ㅛ	ㅜ	ㅠ	ㅡ	ㅣ	

foundation of that ruling class and ultimately of the monarchy itself. The amount of opposition to Hankul from the ruling class was indeed almost insurmountable. Following Sejong’s death, Hankul was relegated quickly to the status of a “vulgar” writing system, used mainly by women and commoners. The situation did not change until the rise of Korean nationalism in the late 19th century. It is against this backdrop that Sejong’s initiative in inventing the Hankul writing system must be understood and appraised.

When the invention of the Hankul writing system was announced in 1443–4, there were 28 letters, four more than in present-day Hankul. Four original letters dropped out of use due to subsequent changes in Korean. The 24 letters used in present-day Hankul are in Table 1.

Three important things need to be noted about the conceptual basis of Hankul, as explained clearly in *Hwunminjeongeumhaylye* (“Explanations and Examples of the Correct Sounds for the Instruction of the People”). First, some of the letters, particularly consonant letters, have a strong articulatory basis in their formal design. For example, consider the letter symbols for /k/ and /n/. In order to produce /k/, the back of the tongue must be raised so that it comes into contact with the soft palate or velum. The outline of the tongue in that position served as the basis for the shape of the letter ㄱ. The sound unit of /n/, in contrast, is produced by putting the tip or blade of the tongue against the upper front teeth. The outline of the tongue in that position formed the basis for the shape of the letter ㄴ. Second, this articulatory orientation is augmented by the way some of the “complex” letters were designed on the basis of “simple” letters. Common phonetic properties—or distinctive features, in phonology parlance—are consistently indicated by strokes added to basic letters. For instance, the difference between the lax and aspirated stops in Korean (i.e., /p, t, c, k/ vs. /ph, th, ch, kh/) is aspiration or a strong puff of air. The lax stops don’t have this property whereas the aspirated stops do. The presence of aspiration is marked by the addition of the same vertical stroke to the letter symbols for the lax stops. The letter symbols for /t/ and /k/ are ㄷ and ㄱ, respectively, and those for /th/ and /kh/, that is, ㅌ and ㅋ, respectively, are based on the former letters with the addition of the same horizontal stroke in appropriate places. The third point concerns the fact that the same consonant letters are used regardless of whether they appear in syllable-initial or syllable-final positions. For instance, the same letter symbol ㄱ is used whether it begins or ends a syllable. This may sound like too obvious a point, but this fact was not recognized in the received Chinese scholarly view prior to, and at the time of, the invention of Hankul. More importantly, the concept of abstract sound units or phonemes was well understood in the creation of Hankul. For example, the same symbol ㅅ is used to represent two different realizations (i.e., allophones) of the same phoneme /s/. This phoneme is pronounced either as [ʃ] before the front high vowel /i/ or as [s] before other vowels. This difference is “ignored” in Hankul as, being contextually determined, it does not contribute to meaning (i.e., the very concept of phoneme in modern phonology). These and other characteristics must be regarded as an insightful discovery on the part of Sejong himself.

Table 2 Hankul: the complete set

Consonants																			
ㄱ	ㅋ	ㄴ	ㄷ	ㄸ	ㄹ	ㅁ	ㅂ	ㅅ	ㅆ	ㅇ	ㅈ	ㅊ	ㅊ	ㅊ	ㅊ	ㅊ	ㅊ	ㅊ	ㅊ
Vowels																			
ㅏ	ㅑ	ㅓ	ㅕ	ㅗ	ㅛ	ㅜ	ㅠ	ㅡ	ㅣ	ㅚ	ㅜ	ㅛ	ㅜ	ㅠ	ㅜ	ㅠ	ㅜ	ㅠ	ㅜ

Hankul is said to have only 24 letters (Table 1). There are in reality as many as 40 letters in all (Table 2). However, the popular claim that Hankul has only 24 has some truth in it in that the additional 16 are not produced *ex nihilo* but on the basis of the “basic” letters in Table 1. The design of some of the additional letters is also well motivated in phonetic terms. The letters for the tensed stops (and tensed fricatives) are a case in point. When the tensed stops are produced in Korean, the airstream is blocked not only at the place of articulation, for example [pp] at the lips, but also at the vocal cords. This property of the tensed stops is represented in Hankul by “doubling” on the lax stop letters. For example, the symbol for /pp/ is designed by the juxtaposing two instances of the symbol for /p/, i.e., ㅍㅍ vs. ㅍ.

Finally, mention must be made of “the block principle” in Hankul. Sounds combine with one another to form larger units known as syllables. Syllables are made up of one vowel and one or more optional non-vowel sounds, that is, consonants and semivowels. The concept of syllable plays an important role in Hankul. Instead of appearing in a linear fashion (like English), Hankul letters are assembled into graphic blocks. For example, consider the word *tal* ‘moon’. Instead of arranging the three letters for /t/, /a/, and /l/ in a linear manner as in the romanized rendition *tal*, the block principle ensures that these letters be all represented in a single graphic block. The word *tal* is written as 달. The block principle makes good sense in view of the fact that, when Hankul was invented, the predominant writing system was that of Chinese characters, which were (and are) written in graphic blocks. Hankul began to be used—and still is to a certain extent—in conjunction with Chinese characters. Thus it was almost inevitable for the Hankul letters to be written in graphic blocks in line with Chinese characters.

Self-Access and Independent Learning Centers

HAYO REINDERS

Introduction

Self-access centers (SACs) are learner-oriented language learning environments that encourage the development of learner autonomy. SACs provide materials, activities, and staff support to help learners develop the skills necessary for taking control over the content, pace, and method of their learning. SACs do not have to be physical spaces (although in practice they often are); increasingly, learning environments are being designed that either combine a physical space with an online *support* system or provide all elements of self-access online (see, e.g., Alford & Pachler, 2007; Conacher & Kelly-Holmes, 2007; “My English” in the online resources section below). SACs are especially common at tertiary institutions, although they exist at all other school levels, including in primary schools.

Self-Access Pedagogy

SACs developed from the early 1970s as one practical manifestation of the development from behaviorist to constructivist and humanist approaches to learning. In many cases, SACs have replaced existing language laboratories to offer an environment where the focus is firmly on the individual learner and on encouraging learners to take responsibility for their own learning process. SACs do not generally offer set materials or a curriculum, and teacher involvement is mostly limited to *supporting* individual learners and to *facilitating* the (self-)study process (Lamb & Reinders, 2006).

SACs are not only different from the teacher-controlled laboratories they replaced but are also not simply a specialized type of library. Libraries are repositories of information, and although SACs contain a large number of materials and systems for retrieving them, their focus is on the learning process and on supporting this, rather than merely on the provision of information. Another misconception is that self-access learning is the same as self-study. Although a great deal of learning in a SAC is generally done individually, most centers offer spaces and activities for learners to work together. Some organize language exchanges, pair students to work together, or offer materials and activities that require group work.

Although SACs aim to develop autonomy, self-access learning is not necessarily autonomous learning. It is possible for students to simply do their homework there or to follow the teacher’s instructions. SACs are often used for remedial purposes, when students are given materials appropriate to their level and interest in order to catch up with the rest of the class. In other words, different types of learning (and even teaching) are possible in a SAC.

Elements of Self-Access Centers

The most immediately recognizable element of a SAC or (online) system is the provision of materials. The selection, creation, and adaptation of materials for self-access is different from that for classroom teaching. As the materials are generally chosen and used by students themselves, they need to be clearly described in terms of their level, their content, and many other aspects, and then recorded in a way that facilitates student access to this information. Commonly this is done through the use of a computer database that students can search by using specific parameters. In addition, materials are usually coded by color or in some other way, and placed together by topic or level so as to provide easy access. Materials also need to be self-contained, meaning that they need to include all the information and ancillary materials necessary to allow learners to use them without the help of a teacher. This means that the instructions need to be comprehensive, that sufficient explanation needs to be given, and that answer sheets and feedback mechanisms need to be included. When evaluating SACs, it is important to determine whether the materials have been successfully adapted for self-learning. It is not uncommon to find materials for self-study (Jones, 1993) or for self-access (Reinders & Lewis, 2006) that offer students little support to work without the help of a teacher and that fail to include advice on analyzing needs, setting goals, or monitoring improvement.

Another common element of SACs is the provision of language learning activities. These include pair work such as language exchanges and "study buddy" programs, as well as group activities such as "discussion groups," "movie clubs," and "reading circles." Some centers also offer workshops, usually with some focus on improving learning skills (as opposed to the development of language skills only). For example, a workshop on writing skills might focus on ways of proofreading or getting feedback from others, rather than (only) on the elements of a good essay.

Perhaps the defining element of SACs is their focus on the development of learner autonomy. A range of methods is used to increase students' awareness of the language learning process and their own role therein. Most SACs offer some kind of needs analysis, ranging from self-assessment sheets to large-scale institutional assessments. Most also offer instruments for setting and keeping track of learning goals. These can be in the form of a learning diary or an (online) portfolio and in some cases include computer monitoring of learning activities and improvement. The provision of strategy instruction, either through workshops or through self-study worksheets, is also common. In many cases there is some focus on the development of metacognitive strategies, such as those needed for planning one's learning and monitoring progress. Finally, in some centers students' learning is actively monitored by an adviser (see below) or with the help of the computer. For example, the Electronic Learning Environment at the University of Auckland records the amount and type of learning and matches this with the student's language needs. Where a mismatch is detected, the computer will prompt the learner to change either their goals or their learning behavior (Reinders, 2007). Such systems are becoming more common and are in some cases replacing the SAC as a physical center with a completely online system.

Many centers also include language advising or language counseling sessions (although sometimes these are offered as a stand-alone service) (Mynard & Carson, 2012). A language advisory session is a meeting between a student and an adviser with the aim of improving the language learning experience for the student. An adviser and a student may, for example, work together to identify the student's learning needs and to identify the most appropriate resources and learning strategies, and the adviser may give feedback on learning progress. The eventual aim of such sessions is to encourage the students to reflect on their own learning, and to gradually ask them to make all decisions of the learning process by themselves.

Benefits of Self-Access

The purported benefits of self-access include its flexibility in allowing learners to study whenever, however, and (in the case of online self-access) wherever they want. Self-access can offer learning opportunities where traditional courses are unavailable or not feasible because of students' time constraints, or because institutional language needs are too great or diverse to be met through regular classroom education. The pedagogical benefit of the greater control learners have in self-access is the increased individualization of the learning process; students can work on those areas that are relevant to them, and may therefore be more motivated to continue their learning outside the classroom, or to see a stronger connection between their classroom and out-of-class learning.

There have also been claims about the potential for self-access to lower the costs of language education. In practice, however, this is often not the case. SACs still need to be staffed with language advisers and need constant updating of their materials, as well as extensive technical support. They are rich in materials and technology and therefore expensive to establish and maintain. Some SACs are established mainly to reduce the number of classroom teaching hours, and learners are not given sufficient support. In these cases, the SAC functions more as a computer room or homework center and the pedagogic benefits are minimized.

The most important potential benefit of self-access is its contribution to the development of learner autonomy. SACs are intended to focus students' attention on the learning *process* and encourage them to become responsible for managing their own learning. Learners can develop the skills to plan and monitor their own learning, find their own resources to support themselves, and learn to work with other learners. In this way, SACs have the potential to empower and help students prepare for their lifelong learning.

Self-Assessment

SARI LUOMA

Self-assessment of second or foreign-language ability refers to the language learner's evaluation of his or her own language skills, usually in connection with a language course or as part of other forms of language assessment. Self-assessments typically ask students to respond to closed or open-ended questions or "can do" statements to indicate how well they feel they can perform in the language. In classrooms, self-assessment activities may also include learner diaries, self-reports, and periodic self-assessment of achievement of course goals, as well as learners' contributions to portfolios. Sometimes self-assessment is conducted directly after learners perform a language task by asking students to rate their own performance according to specific criteria. Self-assessment can be used to increase students' awareness of the criteria by which teachers and others judge their language skills. Sometimes self-assessment is also used in language research when multiple observations of language ability are needed, or as a quick method to get a rough estimate of respondents' language skills in large-scale surveys, as in the Eurobarometer studies (e.g., European Commission, 2001). This entry concentrates on the use of self-assessment for learning-oriented purposes.

Background

Epistemologically, the rise of self-assessment in education is associated with the rise of sociocultural theory in education (Gipps, 1999). Sociocultural approaches contrast with the traditional, hierarchical concept of teaching where the expert teacher transmits knowledge to the pupil and accordingly exerts the power of the expert in examining the students' knowledge. Sociocultural approaches, in contrast, emphasize the role of the learner and the learning community in the learning process and outcomes. From this perspective, learners should also be engaged in the assessment process with the aim of sharing power and responsibility with them and, ideally, producing engaged, motivated learners who monitor themselves and who are aware of their goals and in charge of their learning (Broadfoot, 1996). As the learner becomes more engaged and empowered in the learning and assessment cycle, the teacher's role in this approach becomes that of a guide and supporter. Self-assessment is an important tool to engender this engaged participation (Black & Wiliam, 1998).

Many proponents of self-assessment in language education, including Oscarson (1997) and Little (2005), point out that the development of self-directedness needs to proceed in small steps and with careful guidance from the teacher. Otherwise, as exemplified in studies quoted by Gipps (1999), learners will find self-assessment challenging and therefore perhaps not very appealing. When support is given, however, as exemplified by Hasselgreen (2003) and Little (2005) among others, even primary-grade students can develop an autonomous learning style through repeated, concrete self-assessment tasks answered with the help of the teacher; associated goal-setting for next steps of learning at a concrete level; and periodic summaries of these assessments to look back on the students' progression of achievement.

Some Prominent Examples

Self-assessment started to be promoted in language education relatively late, compared to other fields of education and research. One of the early efforts was coordinated by the Council of Europe in the early 1970s. A working group within the Council developed a communicatively oriented system for adult foreign-language learning with a strong emphasis on learner autonomy. They first defined the outline of an adult-oriented language-learning program called the threshold level (Van Ek, 1980). The threshold level did not include actual self-assessment instruments, but it defined in detail the acts that the language learner should be able to accomplish in order to act *independently* in the target language environment (early “can do” statements). Soon afterwards, the Council also published the first compilation of suggested self-assessment questionnaires for language learning (Oscarson, 1978). Subsequent developments of the Council of Europe’s work include:

- The Common European Framework of Reference (CEFR; www.coe.int/t/dg4/linguistic/cadre_en.asp), which includes self-assessment as an integral component of the envisioned learning path and specific advice for considering the place of self-assessment in the learning course (Council of Europe, 2001; full text also available from the link at the Council of Europe portfolio Web site: www.coe.int/portfolio). The CEFR presents a self-assessment grid where the Council of Europe’s six proficiency levels are defined in short statements for comprehension (listening and reading), speaking (spoken interaction and spoken production), and writing. The appendixes include more detailed DIALANG self-assessment statements for listening, reading, and writing, as well as the ALTE “can do” statements for listening/speaking, reading, and writing, which are meant for the use of educators who are helping language learners achieve their goals (ALTE, 2002; www.alte.org/cando/).
- The European language portfolio (ELP) (www.coe.int/portfolio; Council for Cultural Cooperation, 1997; Schneider & Lenz, 2001), which is a three-part document intended to support and verify a learner’s accomplishments in language learning. It includes a language passport, a language learning biography, and a dossier where learners can display their work in all the languages they know. Self-assessment forms a prominent part of the “language passport,” which opens with a self-assessment grid that covers the CEFR self-assessment categories listed above. The intention is that the learner regularly updates this grid for each language that he or she knows (see also www.coe.int/t/dg4/portfolio).
- DIALANG (www.dialang.org; Huhta et al., 2002), a computer-based diagnostic language assessment system for fourteen European languages. Self-assessment features prominently in the DIALANG design. If users choose a test of listening, reading, or writing, they are asked to self-assess their abilities before starting the test by answering 18 can do statements. The self-assessment is used in assigning them to one of three levels of test difficulty. When the test is completed, the users get feedback on the test results as well as the degree of match between their self-assessment and test performance. They may also choose to view advice on possible reasons for mismatches.

Parallel to the Council of Europe work, self-assessment practices and methods were also developed in other learner-oriented language learning frameworks. A classic American example is Chamot and O’Malley’s (1994) CALLA framework. CALLA is a cognitive approach to language teaching that is based on explicit teaching of learning strategies. Self-assessment forms the core of metacognitive strategies, which include planning, monitoring, and evaluating. Monitoring encompasses students checking for comprehension and evaluating their own comprehension and production during task performance.

Evaluation forms its own phase in the CALLA lesson sequence, during which students are asked to explicitly reflect on what they have just learned and evaluate how well they have learned it, how well the strategies they used worked for them, and what they might want to do differently next time they meet a task like this. The evaluation is conducted through simple, structured forms as part of the CALLA classroom routine.

Self-assessment also plays a central role in constructivist approaches to assessment, especially portfolio assessment. The language learner's portfolio is a broad, student-assembled collection of tasks that represent the student's language learning from a defined period, such as a course, a school semester, or even a multi-year language-learning program. In addition to final products, the portfolio may include successive drafts of a particular piece, self-evaluations, and journal accounts of learning processes. It should include an explanation of criteria for choosing particular pieces to display, a reflection of the student's learning process, an evaluation of its successfulness, and plans for future learning goals (Paulson, Paulson, & Meyer, 1991). Similar to the CALLA approach, the focus in portfolio assessment is on the development of learner autonomy through improved self-monitoring and self-evaluation skills.

Questions, Challenges, and Ways Forward

An obvious question about self-assessments is their validity as indicators of learners' language ability. Researchers have investigated this question by comparing self-assessment results to teacher grades or test scores, and the results are mixed. Oscarson (1984), summarizing several studies, found that adult students' self-assessments corresponded fairly well with teacher evaluations, and Hasselgreen (2000) found that with initial support, 11–12-year-old Norwegian students were "almost disconcertingly realistic about what they can and cannot do in English." Chen (2006), studying Taiwanese college students of English, similarly found that the students' self-assessments corresponded well with teacher ratings after the students received training in self-assessment.

In contrast, Patri (2002) investigated self and peer assessment of oral presentation skills in English at a university in Hong Kong and found that when students met in small peer groups to receive feedback on an oral presentation, their peer evaluations matched teacher evaluations fairly closely, whereas the accuracy of their self-assessment did not improve after peer feedback. Noting a pattern of low performers overestimating and high performers underestimating their own and their peers' skills, Patri speculated that the students' perceptions about their own performance were too strong to be influenced by peer feedback, whereas the students more readily changed their peer evaluations upon hearing the views of others. Kaivanpanah and Alavi (2008) investigated Iranian learners' self-assessment of their vocabulary knowledge. Students had to assess how well they knew the meaning of words they likely did not know in three texts. In between two rounds of self-assessment, they completed a vocabulary test that asked them to define the meaning of the same words that the self-assessment questionnaire included. Results indicated that students overestimated their knowledge of unknown words both before and after they completed the vocabulary test, and only very slight improvements were found between the two self-assessments. The researchers suggested that self-assessment may be influenced by culture, as Iranian males turned out to overestimate their vocabulary knowledge significantly more than females, which the authors considered to correspond with their cultural upbringing. The issue of individual and cultural factors influencing self-assessment has also been raised by numerous other researchers (e.g., Oscarson, 1997; Alderson, 2005) and remains an open area of research, especially important in contexts where the comparability of self-assessments between students from diverse backgrounds is of importance.

Another key question in self-assessment is whether there is systematic variation between self-assessments either in terms of the methods used to derive the self-assessment or the skills being assessed. Ross (1998) investigated this question by conducting a meta-analysis of 60 studies that compared self-assessments and external assessments and combining this with an original empirical study on the accuracy of student self-assessments during a learning course. Based on earlier studies, he suggested that learners are likely to provide more accurate self-assessments (using external assessments as criteria) if they respond to can do statements that define concrete language use experiences that are familiar to the learners than if they are asked to use a proficiency scale with more abstract definitions of language skills. His meta-analysis indicated that students were more apt at self-evaluating their reading and listening skills than their speaking and writing skills, though notably, the correlation coefficients between self-assessments and other measures for listening varied widely between studies. He explained the findings by noting that self-assessment statements typically describe contextualized language use situations, and students may have many more such experiences with listening and reading than with speaking and writing.

During the past ten years, conceptual developments in self-assessment in language learning seem to have reached a plateau. Most of the substantial studies referenced in this entry were written in the last two decades of the 20th century. The newer studies, while proposing new instruments, have not brought up any significant advances in the theory or practice of self-assessment. Neither have new proposals for self-assessment use arisen recently from the area of learning-oriented language assessment. This may be because the current research base offers reasonable support to the ways self-assessment is used in the service of language learning, so there is little urgency to develop better tools or to understand better how to interpret and use the results. Or, new developments might be just around the corner. For example, in connection with the CEFR-related studies, Little (2005) raises the question of whether the can do statements focus too much on tasks and too little on the quality of language needed to address the tasks effectively, such as grammatical accuracy, phonological control, or sociolinguistic appropriateness. Such evaluations are typically made by language teachers, and it will be interesting to see whether it is possible to develop effective self-assessment instruments for the same purpose (see www.beds.ac.uk/research/bmri/crella/cando for an English profile can do project). Another recent proposal by Alderson (2005) reintroduces Bachman and Palmer's (1989) suggestion of perhaps developing negatively worded self-assessment statements ("I cannot (yet) do X" or "I have difficulty doing Y") for diagnostic purposes. Such applications of self-assessment in new contexts and purposes might provide interesting results in the future.

Selinker, Larry

LYNNE STALLINGS

What I gradually realized was that no matter what we did . . . my Yiddish-speaking grandmother, in the United States about 50 years . . . , could not be understood by her grandkids who only wanted to speak English. . . . But some in that ghetto could do better than others. . . . I remember wondering: “What’s going on here?”; “Why can’t she do that?”; “How can this be?” All these issues still intrigue and excite me. (Selinker, 2006, p. 201)

Larry Selinker (1937–), Emeritus Professor of Applied Linguistics at the University of Michigan, writes this scenario and its corresponding questions to reflect what he calls “the fossilization puzzle,” in which the majority of language learners fail to achieve the language abilities of a native speaker. It is this puzzle that has provided the impetus for his career and the significant contributions he has made to the field of second language acquisition (SLA), a remarkable accomplishment given that SLA was not yet a field in the early 1960s when he began his graduate studies.

As an undergraduate studying Hebrew language and literature at Brandeis University in the 1950s, Selinker took advantage of early opportunities for hands-on experience with language learning and teaching, studying abroad in Israel in his junior year, teaching English in the Republic of Guinea after completing his master’s degree in linguistics at American University, and then teaching English for foreign students. Since then, Selinker has held primary teaching positions at the Universities of Washington, Michigan, and London, and has taught linguistics and applied linguistics courses as well as English Institute courses.

While some of Selinker’s most prominent work, as captured by the scenario above, centers on language transfer, interlanguage, and fossilization, which are detailed below, a significant part of his early experience was shaped by his teaching at the University of Washington, where he and Louis Trimble were asked to teach English for science and technology (EST) courses in the Engineering Department. What began as specialized teaching courses resulted in large-scale research projects about the discourse of science and technology, resulting in collaborative articles about EST (e.g., Selinker & Trimble, 1974; Selinker, Todd-Trimble, & Trimble, 1978).

As a PhD student at Georgetown University, Selinker was a student of Robert Lado, whose 1957 article set forth procedures, via contrastive analysis (CA), for making comparisons between a learner’s native language (NL) and the target language (TL), suggesting that differences would allow observers to make predictions about learners’ errors. In Lado’s CA courses, therefore, Selinker and his peers compared first and second language systems, predicting what parts of the native language the learners would “tend to transfer” to the TL (Lado, 1957, in Selinker, 1992, p. 7). In the early 1960s, however, with the field reflecting on Noam Chomsky’s critique (1959) of B. F. Skinner (1957), the theoretical underpinnings of the field were shifting from behaviorist principles to more cognitive-based principles. Following this shift, although Selinker and his peers frequently challenged Lado that “the contrastive analysis thing was wrong,” they learned a valuable lesson from Lado, who “had his students go out and empirically test [the hypotheses]” (Selinker, 1996).

In his dissertation, Selinker followed Lado's advice, continuing on to explore "linguistic and psychological factors involved in language transfer" (Gass & Selinker, 1993, p. 5). Testing the extent to which Israeli Hebrew teens transferred NL word order of object, time, and place expressions (e.g., I bought downtown the postcard) to the target language, English (e.g., I bought the postcard downtown), Selinker did find effects of NL transfer on the TL, but also concluded, among others (see Nemser, 1971 and Corder, 1967, cited in Selinker, 1972), that the NL-TL dichotomy was insufficient in predicting what errors learners would make.

During a Fulbright Fellowship with Pit Corder at the University of Edinburgh (1968-9), Selinker addressed that gap, asserting that the learner must, in addition to the NL and TL, have an interlanguage (IL). Specifically, Selinker defined interlanguage as "a separate linguistic system based on the observable output which results from a learner's attempted production of a TL norm" (1972, p. 117). In interlanguage, the learner is neither using the NL nor the TL, but instead a system with its own set of grammatical rules. Selinker provides the example of a native Hebrew speaker who, although fluent in English, would produce the sentence, "What did he intended to say?" (emphasis added), when speaking English. This sentence reflected neither English nor Hebrew syntax, and was thus part of the learner's interlanguage system.

Furthermore, Selinker (1972) identifies at least five second language learning processes that explain IL behavior: language transfer, transfer of training, second language learning, strategies of second language communication, and overgeneralization of TL linguistic material (1972, p. 118). To illustrate these processes, the language transfer process, for example, might result in a learner transferring a sound from the NL to the TL. Thus, Selinker provides the example of a French learner of English who uses the French /r/ (a uvular sound) when pronouncing English words with "r" in them (1972, p. 119). In addition, the interlanguage example in the previous paragraph represents the overgeneralization process whereby learners overgeneralize rules to the TL such as the past tense morpheme "-ed" (p. 121).

Selinker explains that an adequate second language theory must also account for the fact that a majority of learners, like his grandmother, continue to produce incorrect structures in the TL even after they have been learned. To account for such observational data, Selinker introduces and defines fossilization, whereby learners "will tend to keep . . . surface linguistic material . . . in their IL productive performance, no matter what the age of the learner or the amount of instruction he receives in the TL" (1972, p. 134).

These seminal pieces of research have undoubtedly influenced second language acquisition studies, moving the field beyond the NL-TL dichotomy that was present in CA, but also resulting in several related publications that served to forward and refine Selinker's ideas. Another noteworthy publication by Selinker is *Rediscovering Interlanguage* (1992). Published 20 years after Selinker's first interlanguage article, the premise of the book is to help the field more clearly understand IL by relating it to historical texts in the field. Borrowing from Garfinkel (1967, cited in Selinker, 1992), Selinker adopts a "purposeful misreading" methodology to read foundational texts in CA, error analysis (EA), and bilingualism, for example, from fresh perspectives (Selinker, 1992, p. 4). He is careful to note that in rereading texts, readers should take care not to focus on the "defects [which] lead . . . to the infamous 'baby and bathwater syndrome'" (Selinker, 1992, p. 3).

To illustrate Selinker's approach, consider CA as a case in point. Selinker acknowledges that he was "part of the unfortunate movement that threw out the contr[astive] analysis baby with the bathwater" in the 1960s (Selinker, 1996), admitting that most CA research has since been disregarded:

It is a pity that the CA literature, especially the CA dissertation literature, is a buried literature and thus so unknown. It is perhaps an intellectual tragedy of sorts, since so much detail is worked out in this literature . . . from this literature, the interested language teacher or SLA researcher can create scores of testable hypotheses about what L2 learners are doing and be helped by CA detail to investigate IL. (Selinker, 1992, p. 97)

Nonetheless, he demonstrates how a purposeful misreading approach might show the value of CA and, in particular, "how rich a theory [Lado] really had" (Selinker, 1996). Explaining that CA was rejected because of strong statements that promised too much (e.g., "The learner will do X or Y," Selinker, 1992, p. 3), Selinker revisited Lado's work, examining his work for hypotheses that might prove useful for SLA theory today. More specifically, he revisited Lado's work from an IL perspective, noticing that a learner's language inherently contains variation. With the knowledge of IL variation in mind, Selinker reframed Lado's strong statements to create hypotheses that could be empirically tested: "a learner *might* do X and/or Y under Z conditions" (Selinker, 1992, p. 4).

In another example, Selinker considers data from his 1960 unpublished MA thesis (cited in Selinker, 1992), designed to "predict some of the difficulties that speakers of Israeli Hebrew (IH) *might* have learning English" (1992, p. 100). Using phonological patterns identified in IH and English, Selinker compares NL Hebrew sounds with TL English sounds, a common approach taken in contrastive analysis. But rather than confining himself to the comparisons and strong statements associated with CA, he uses the data to show that hypotheses about an IL could be articulated and tested. For example, when comparing Hebrew and English, one notices that the bilabial /w/ exists in English, but not in Hebrew. As a result, a prediction is made that producing /w/ in the IL will be difficult. Yet Selinker argues that these types of hypotheses have not been empirically tested, leaving the SLA literature without some fundamental truths. Thus, Selinker asked the audience at the 1990 Georgetown University Roundtable on Languages and Linguistics: "[C]an we continue to ignore the rich reframed IL detail of our CA predecessors and, thus, in a historical sense, continue to trivialize our own attempts at SLA theory making?" (Selinker, 1990, p. 142).

In *Rediscovering Interlanguage*, Selinker (1992) provides evidence that his answer to the question is an unqualified "No," not only for CA but in other areas of language learning as well. With this implied charge to consider the history of the field and rethink how we approach research, it is evident that Selinker's path to solving the fossilization puzzle extends beyond language transfer, interlanguage, and fossilization. While these areas are undoubtedly important to the field of second language acquisition, we benefit equally, if not more, from Selinker's reminders to conduct empirical research just as Lado taught him when the field of SLA was emerging.

Semantic Prosody

WINNIE CHENG

Semantic prosody refers to the attitudinal meaning, often pragmatic, of a lexical item. Attitudinal and pragmatic meaning are multifaceted and therefore semantic prosody has been characterized in a variety of ways by researchers (Whitsitt, 2005; Hunston, 2007; Stewart, 2010). The various facets of the definition of semantic prosody are evident from a chronological review of linguists' work on this aspect of language (Stewart, 2010).

A Chronological Review

When describing a word form that was likely to be followed by something positive or negative, Sinclair (1987) referred to "good/positive" or "bad/negative" semantic profiles. For instance, Sinclair pointed out a specific lexicogrammatical environment, or "semantic environment" (1987, p. 112), of the phrasal verb *set in*, noting that the subjects of this phrasal verb always referred to some unpleasant states of affairs, such as *rot*, *decay*, *despair*, or *bitterness*, and so *set in* is described as having a bad semantic profile (pp. 155–6). The co-occurrence of the most frequent collocates and *set in* thus created a negative default value, which explained both semantic associations of words and speakers' attitudes about their choice of words.

This phenomenon was termed "semantic prosody" by Louw (1993, p. 157) when he linked semantic prosody to Firth's (1957) phonological prosody due to a process of "phonological colouring" (Louw, 1993, p. 158). Louw defined semantic prosody as a "consistent aura of meaning with which a form is imbued by its collocates" (p. 157), and so the words *utterly*, *bent on*, and *symptomatic of*, which were followed by *destroying*, *ruining*, *clinical*, *depression*, and *multitude of sins*, were imbued with undesirable meanings due to a transfer of meaning from their habitual co-text. Semantic prosodies were seen as "reflections of either pejorative or ameliorative [semantic] changes [over a period of time]" (p. 169) that were based on frequent forms that "can bifurcate into 'good' and 'bad'" (p. 171). Louw (1993) also pointed out the diachronic nature of semantic prosodies, remarking that semantic prosodies were "the product of a long period of refinements through historical change" (p. 164).

Bublitz (1996) observed that "Words can have a specific halo or profile, which may be positive, pleasant and good, or else negative, unpleasant and bad," similar to Louw's (1993) "aura of meaning," and that semantic prosody refers to negative or positive semantic coloring of node and collocate (Bublitz, 1996, p. 9).

Stubbs (1995) examined the semantic prosody of a great number of words, including *accost*, *amid*, *amusement*, *backdrop*, *care*, *cause*, *commit*, *community*, *deadlock*, *distinctly*, *soar*, *heritage*, *lavish*, *loiter*, *lurk*, *proper*, *provide*, *somewhat*, *standard*, *undergo*, and *untold*, and shifted to the term "discourse prosody" from "semantic prosody" in order to better describe the discourse and pragmatic functions of semantic prosody.

Sinclair (1996) developed the notion of "semantic prosody" in his model of five categories of co-collection of the lexical item/unit of meaning: Semantic prosody and the core were obligatory categories and collocation, colligation, and semantic preference optional

2 SEMANTIC PROSODY

categories. Sinclair defined “semantic prosody” as “attitudinal, and on the pragmatic side of the semantic/pragmatics continuum . . . It expresses something close to the ‘function’ of an item—it shows how the rest of the item is to be interpreted functionally. Without it, the string of words just ‘means’—it is not put to use in a viable communication” (1996, pp. 87–8).

In fact, semantic prosody came to be regarded as the most important of all, as “the selection of the item is controlled by the prosody, because the whole point of expressing oneself in this way is to pre-evaluate the actions, which would otherwise be evaluated positively by the reader/listener” (Sinclair, 2004, p. 175). From the point of view of the speaker/writer, the textual process of constructing a lexical item was described as follows:

1. First the speaker/writer selects a semantic prosody of *x* applied to a semantic preference *y*.
2. The semantic preference in turn controls the collocational and colligational patterns.
3. The final component of the lexical item is the (invariable) core. (Sinclair, 2004, p. 34)

Thus Sinclair (2004, p. 34) suggested that “the initial choice of semantic prosody is the functional choice which links meaning to purpose; all subsequent choices within the lexical item relate back to the prosody.” For instance, the “textual sequence” (p. 34) of Sinclair’s (1991, 2004) “the naked eye” as a lexical item is described as follows:

The speaker/writer selects a prosody of difficulty applied to a semantic preference of visibility. The semantic preference controls the collocational and colligational patterns, and is divided into verbs, typically *see*, and adjectives, typically *visible*. With *see*, etc., there is a strong colligation with modals—particularly *can*, *could* in the expression of difficulty—and with the preposition *with* to link with the final segment. With *visible*, etc., the pattern of collocation is principally with degree adverbs, and the negative morpheme *in-*; the following preposition is *to*. The final component of the item is the *core*, the almost invariable phrase *the naked eye*. (Sinclair, 2004, p. 34)

Partington (2004, pp. 131–2) defined semantic prosody as a kind of evaluative meaning which was “spread over a unit of language which potentially goes well beyond the single orthographic word and is much less evident to the naked eye.” Coffin, Hewings, and O’Halloran (2004) defined the term as “The way in which apparently neutral terms come to carry positive or negative associations through regularly occurring in particular collocations” (p. xxi).

In Hoey’s (2005) work on “lexical priming,” words and word sequences were primed for “pragmatic association” (pp. 26–9); for instance, the property of “vagueness” was associated with “sixty,” which co-occurred with *about*, *around*, *almost*, *up to*, and *getting on for* (pp. 26–7). Baker, Hardie, and McEnery (2006) define semantic prosody as “the way that words in a corpus can collocate with a related set of words or phrases, often revealing (hidden) attitudes” (p. 58).

Features of Semantic Prosody

Hunston (2007, p. 250) identifies a few “sites of disagreement” regarding the features of semantic prosody, namely (a) “the issue of whether semantic prosody is to be regarded as the property of a word/expression or of a longer unit of meaning”; (b) “whether semantic prosody’s attitudinal meaning is best expressed as a binary distinction (positive vs. negative, favourable vs. unfavourable) or whether its characterization should ideally be conceptually more specific”; (c) “the question of whether semantic prosody can ‘carry

over' from one context to another"; and (d) whether the semantic prosody is a type of meaning or a type of semantic or pragmatic process.

Very recently, Stewart (2010) gave a summary of features of semantic prosody, many of which are observed to stem from either Sinclair's or Louw's tradition. Features from Sinclair's approach are that:

- it is central to the unit of meaning, one of the two obligatory elements;
- it is considered within a synchronic framework;
- it is a feature of a unit which is larger than the single word/expression;
- it is not restricted to semantically "neutral" lexical items; and
- it is not restricted to descriptions in terms of "good" or "bad."

Features from Louw's approach are that:

- it is transferred or attached meaning;
- it is considered within both a diachronic and a synchronic framework;
- it is a feature of the word;
- it is associated above all with more semantically "neutral" lexical items; and
- it is generally expressed by means of a binary distinction whose primary terms are "good" and "bad" (positive/negative, favorable/unfavorable). (Stewart, 2010, p. 161)

Stewart argues that Sinclair's interpretation of "semantic prosody" should be referred to as "discourse prosody" to better capture the function in the discourse, and Louw's interpretation remains to be referred to as "semantic prosody" (2010, p. 161). Stewart therefore suggests that the concept of "semantic prosody" be "profitably split into two concepts, notwithstanding some overlap between the two" (p. 163).

The semantic prosody features reviewed by Stewart (2010) are (a) contributions from scholars on the concept since 1987, with a focus on its evaluative function and its hidden quality; (b) synchronic and diachronic issues; (c) the potential drawbacks of viewing semantic prosody as belonging to the word or part of a longer sequence of words; and (d) issues regarding inferring semantic prosody from concordances from corpus data. Some of the features (Hunston, 2007; Stewart, 2010) will be further described in the following.

Evaluative or Attitudinal Function

Stewart observes that "the evaluative quality of lexical items described as being associated with semantic prosody is not always manifest," arguing that some semantic prosody examples in the literature do not actually express any attitudinal function, for example, describing something as visible or invisible to the "naked eye" (Sinclair, 2004) could be heard as a statement of fact rather than an evaluation or attitude (Stewart, 2010, p. 22).

In addition, semantic prosodies are considered context-dependent and register-dependent. For example, when *load of* is followed by *rubbish*, *nonsense*, and so forth (Louw, 2000), the phrase suggests a negative evaluation, but the same prosody does not apply to "Another Load of Crystal Candy and Cadbury's Chocolate Being Delivered" written on the side of a fleet of delivery trucks, the writer's intention of which may be to get others' attention "through an eye-catching word combination" (Stewart, 2010, p. 23). Another example is the verb "cause," which "loses its association with negative evaluation when it occurs in 'scientific' registers" (Hunston, 2007, p. 263), although such are often individual instances of occurrence rather than the norm. Stewart notes that the evaluative function of semantic prosody is sometimes equated to connotation, expressing "second-order or peripheral meanings" (Stubbs, 1993, p. 35), and yet the connotative aspect is in conflict with Sinclair's

view, that is, semantic prosody plays “a central, pivotal role within the unit of meaning” (Stewart, 2010, p. 40).

Hidden Quality and Semantic Neutrality

Another feature commonly discussed in the literature is the hidden, subliminal, covert, concealed, and subconscious quality of semantic prosodies (Stewart, 2010). Stewart observes that “prosodies are usually attributed to semantically more ‘neutral’ items” (p. 32) because words with inherent semantic neutrality “lend themselves more readily to analyses of any hidden shades of meaning” (pp. 32–3). Examples of words that are characterized by semantic neutrality are “happen,” “cause,” “commit,” “undergo,” “provide,” “somewhat,” “utterly,” “absolutely,” and phrasal verbs such as “set in,” “break out,” “sit through,” “come about,” “bring about,” and “fork out” (p. 32). In comparison, “semantic prosodies characterising more obviously positive or negative items . . . are relatively uncommon” (p. 33), with the exceptions of, for instance, “rife” (Partington, 1998, p. 67), “reckless” (Stubbs, 2001, p. 85), and “fickle” (Tognini-Bonelli, 2001, pp. 19–21).

Diachronic and Synchronic Process

A debated feature of semantic prosody is whether semantic prosody is a feature of a word or part of a longer sequence of words (Hunston, 2007; Stewart, 2010). With regard to the diachronic and synchronic process of semantic prosody, very often, semantic prosodies are regarded as metaphorical meaning that “may be attached, be taken on, be taken, be acquired, be accorded, be carried or be held; it may imbue, colour, taint, rub off, be reflected or spill over; further, prosodic meaning is an aura, a halo, a shade or a hue, and is the result of infection or contagion” (Stewart, 2010, p. 43). In this sense, semantic prosody is viewed diachronically, as the focus seems to be on the processes of semantic change; for example, “set in,” “utterly,” and so forth were semantically neutral in the past but have since been habitually co-occurring with semantically, in most cases, negative words, and so have acquired negative semantic evaluative meaning.

As noted by Stewart (2010), however, so far analyses of semantic prosody have been carried out synchronically, in the sense of either using synchronic rather than diachronic corpora (p. 47) or not studying the origins of meaning of words (p. 48). Stewart suggests that instead of interpreting semantic prosody diachronically as “transfers of meaning” that “presumably take place over a period of time” (p. 51), semantic prosody should be viewed synchronically as “*distributed over*, or better, *characteris[ing]* or *belong[ing]* to a unit of meaning/language/discourse” (p. 51). Sinclair’s (1996) definition of semantic prosody as “primary and central to the unit of meaning, and [able to] represent the reason for making the meaning of a word” (p. 54), best illustrates the synchronic framework.

This synchronic view about semantic prosody involves both node and co-text, that is, the entire unit of meaning that is “selected by the speaker/writer *en bloc* on the basis of its global meaning” (Stewart, 2010, p. 60). In other words, semantic prosody neither belongs to “the node and can be traced back to the co-text,” nor has meaning “passed during the course of time from the co-text to the node” (p. 60).

Property of a Word or a Longer Unit of Meaning

The second discrepancy involves whether semantic prosody is “a feature of (i) a word alone, or (ii) a word + co-text, i.e. the broader environment” (Stewart, 2010, p. 57). Examples of the first alternative include: “*affect* has a clearly negative prosody” (Stubbs, 1995, p. 45) and “Another word which has an unfavourable semantic prosody is the adjective *rife*” (Partington, 1998, p. 67). The second alternative can be illustrated with Sinclair’s (1996, p. 90) “true feelings,” where the expression is the core of a compound lexical item which

has the following inherent components: a semantic prosody of reluctance–inability, a semantic preference of expression (and a strong colligation of a verb with the semantic preference), a colligating possessive adjective, and the core. As remarked by Sinclair (1996, pp. 87–8), “semantic prosody has a leading role to play in the integration of an item with its surroundings.” In his analysis of “regime,” for example, Sinclair (2003, pp. 17–21) classifies “changes” in the concordance line *changes if his twenty-year old regime is to survive. This month marks the* as good, with the explanation that “changes have to be made, which implies that the regime is not good” (p. 19), and so changes are needed to improve the bad regime. This shows that reference is made to specific co-text or context, rather than simply considering “whether changes were conventionally favourable or unfavourable” (Stewart, 2010, p. 98).

Inferring Semantic Prosody from Concordances

Stewart (2010, p. 160) raises objections to “the traditionally tight link between semantic prosody and corpus data,” as illustrated in, for example, “semantic prosody can be observed only by looking at a large number of instances of a word or phrase, because it relies on the typical use of a word or phrase” (Hunston, 2001, p. 142), and “[the study of semantic prosody] has only become possible with the advent of large corpora and suitable software” (Adolphs & Carter, 2002, p. 7). Stewart (2010) argues that semantic prosody, as a type of meaning, cannot be “observed,” suggesting that “The ‘exposure’ of data in a concordance may give the impression that meaning can be seen and observed” (p. 107). In fact, what happens is that it is the lexical item’s environment which is “revealed,” and then “the analyst makes inferences from the environment about the presence or absence of a prosody” (p. 81). The issue that Stewart is more concerned about is the claim (e.g. Baker et al., 2006) that semantic prosody is solely about “words in a corpus” (Stewart, 2010, p. 58), and can be observed/revealed “only” by computational methods (p. 81). Stewart argues that semantic prosody can equally be inferred by “non-computational methods, i.e., by elicitation and introspection” (p. 81). Identifying a semantic prosody from corpus data involves two macro-stages: (a) choosing a relevant and appropriate search, and (b) scanning the corpus data retrieved in order to identify collocations and semantic preferences and then “translating” these into a prosody, to convert data into evidence (pp. 83–5). The second stage is, however, highly interpretive and involves subjective judgments about text fragments (p. 85), due not only to individual analysts’ worldviews but also to their approach to “the network of relationships and interactions existing between the various constituents of any given concordance” (p. 91). Such interpretive methods to identify semantic prosody may be inferior to introspection, as, in addition to different analysts’ interpretations that may differ from one another, “frequently hasty categorizations such as ‘pleasant’ and ‘unpleasant’ are the outcome of personal and potentially arbitrary points of view”; the extent of the textual chunks analyzed may be different; and “the relevant meaning of words appearing near the keyword in a concordance may not be clarified by the immediate lexical environment” (p. 103). The complex and highly subjective process of inferring semantic prosody from a corpus is linked to the way concordances are typically presented (Stewart, 2010, pp. 120–1), despite the advantage of discovering patterns of usage and meanings (Stubbs, 2007, p. 155). Stewart discusses the implications of the various ways of determining semantic prosody (2010, pp. 107–18). First, restricting the analysis of semantic prosody to examining five or six words to the right and left of the node in the concordance can lead to speculations about the broader textual environment and not provide sufficient co-text and context for discourse and pragmatic analysis (pp. 107–8). In fact, Koller and Mautner (2004) recommend a span of 25 words to the right and left of the node. Second, the concordance gives an impression of group cohesion and textual unity, and may lead to perceived, and generalized, semantic consistency (Stewart, 2010, pp. 108–13). Third, the constancy and centrality of

the node (key word) laid out in the concordance may lead the researcher to suspend “hunches about the meaning of the keyword and let the co-text take over,” rather than focusing on how words (the node and its co-text) “interact and influence each other constantly” (p. 114). Fourth, visually the node in a concordance is physically separated from its textual environment, and this explains why in the literature the word is perceived as expressing basic meaning and semantic prosody is supplied by the co-text (pp. 115–16).

Conclusion

The concept of “semantic prosody” was introduced in Sinclair’s (1987) “semantic profiles” to account for the phraseological tendency, or “the idiom principle” (Sinclair, 1987), to describe the way words are co-selected by speakers and writers, and developed later in his model of five categories of co-selection of a lexical item. This area of interest in fact began as early as 1966 when Sinclair observed that the word and the lexical item would not always coincide. As both a useful notion and a valuable analytical category, semantic prosody will continue to contribute to research in major fields of applied language studies, including lexicography, text and discourse analysis, pragmatics, and translation (Dam-Jensen & Zethsen, 2008), in a range of sociocultural contexts of interaction.

Sentence and Discourse Processing in Second Language Comprehension

LEAH ROBERTS

Introduction

In applied linguistics (AL), researchers have always been concerned with second language (L2) learners' knowledge of the target language (TL), investigating the development of TL grammar, vocabulary, and phonology, for instance. However, the accumulation of TL knowledge is only part of what a learner comes to know about the new language: L2 acquisition also involves developing the ability to put this knowledge to use in real time, and this is the topic of L2 sentence and discourse processing (or *L2 processing*) research. The focus tends to be on comprehension processes, and comprehending the input in real time involves a complex set of processes.

Listeners and readers do not wait until the end of a sentence or a piece of discourse before they begin to try to interpret the input, but rather do so *incrementally*. In other words, as each word is encountered its meaning is accessed, and an attempt is made to integrate it as quickly as possible into the unfolding discourse representation. This attempt at immediate interpretation can sometimes lead to erroneous analyses of the input, as illustrated by readers' processing difficulty with a classic "garden-path" sentence like *The horse raced past the barn fell*. This sentence causes problems because on encountering the verb *raced*, readers are "led up the garden path" and assume that it is the main verb. However when the verb *fell* is encountered in the input, it becomes clear that the initial interpretation was wrong—it is *fell* that is the main verb—and readers have to reprocess the sentence to come up with the correct relative clause analysis (*The horse that was raced past the barn fell*). Readers therefore show evidence of incremental processing, constantly attempting interpretation as the sentence unfolds in real time, and in doing so, they apply their grammatical and semantic knowledge to the input, and also subject the resulting analysis to pragmatic and world knowledge to ensure a plausible interpretation. At the same time, and on the basis of these ongoing analyses, comprehenders also predict what is likely to come next in the input.

How are these processes affected when a speaker is processing in their L2? As well as providing more details about the nature of the human sentence processing mechanism in general, findings from L2 sentence and discourse comprehension studies can inform debates on issues and questions that are central to AL. For instance, how do L2 learners process the input in comparison to native speakers? To what extent does the first language (L1) influence learners' moment-by-moment processing of the TL? What are the effects of factors such as proficiency, age of acquisition, and differences in working memory capacity?

Researchers in the field of L2 processing often borrow methods from the monolingual sentence/discourse comprehension field, and focus on similar types of constructions: in particular, the processing of ambiguous input and the linking of linguistic elements to each other in sentences and discourse. As well as investigating these types of constructions—which allows for a picture of the processing mechanism at work—L2 processing researchers are also interested in how learners handle sentences that are ungrammatical

in the TL, in order to see how sensitive they are to its structural properties. These broad topics are elaborated on below, illustrated by key findings from studies that have investigated how L2 learners process sentences and discourse in real-time comprehension.

Processing Ambiguities

Much research into L2 sentence comprehension has investigated learners' handling of ambiguous input. This is because investigating comprehenders' moment-by-moment processing decisions when more than one analysis of the input is available gives us an insight into the nature of the processing mechanism. Often, studies focus on learners' processing of garden-path constructions where native speakers' incremental analyses, as described above, can lead them to temporarily misanalyze the input. In an experimental context, it is *comparable* processing difficulty that provides evidence of a "garden-path effect."

For example, consider the sentences in (1a) and (1b).

- (1) a. After Bill drank the water proved to be poisoned.
- b. After Sam arrived the guests began to eat and drink.

During the reading of sentences such as (1a), the noun phrase (NP) *the water* is likely to be initially interpreted as the direct object of the preceding verb *drank*, arguably because structurally, this is the "least-effort" option for the processor (Frazier, 1979). However, when the next word in the input is encountered—the main verb *proved*—it becomes apparent that misanalysis of the NP *the water* has occurred, because the verb *proved* requires a subject, and under this initial analysis, there is no NP available to fulfill the subject role. Therefore the reader is forced to revise the initial grammatical role analysis of *the water*, changing it from direct object of *drank* to the grammatical subject of the verb *proved*.

Evidence of this garden-path effect is found, for example, in reading-time studies where processing difficulty is reflected in readers' slow-downs at the point where it becomes clear that they have misanalyzed the input (e.g., at the verb *proved* in 1a), in comparison to the same point in a sentence where no misanalysis has occurred, for instance in a sentence like (1b). Sentence (1b) contains the verb *arrive*, which, as an intransitive verb, does not subcategorize for a direct object. Drawing on their knowledge of the lexical-semantic properties of intransitive verbs during their real-time processing, this means that readers are unlikely to misanalyze the immediately following NP *the guests* as direct object, in contrast to the NP *the water* in (1a). Thus at the reading of the main verb in the sentences—the disambiguation point—(1b) should be easier, and therefore faster to process, than (1a). Processing models differ in the precise details of the underlying causes of these comparative processing costs, but all assume that such a cost will occur (for an overview and helpful discussion of parsing models see Vasishth & Lewis, 2006).

The fact that readers are garden-pathed in such instances is evidence of incremental processing, and one of the major questions that has been asked of L2 learners is whether they too are able to process the input incrementally, assigning grammatical analyses during real-time comprehension. The overall answer to this question would appear to be yes. Like native speakers, L2 learners of different language backgrounds show reading time slow-downs at the point of disambiguation (at and following encountering the main verb *proved*) for temporarily ambiguous sentences like (1a) (e.g., Juffs & Harrington, 1996). However, not all garden-path sentences are equally difficult to process: Comprehenders' commitment to an analysis during real-time comprehension differs in strength as a function of a range of semantic factors, reflected in different degrees to which processing difficulty is observed. For instance, the more semantically plausible an initial analysis, the more

strongly committed to it comprehenders are, and therefore the more difficulty they have in recovering from misanalysis (e.g., Christianson, Hollingworth, Halliwell, & Ferreira, 2001).

Like native speakers, L2 learners' online commitments to certain analyses have been found to be sensitive to such semantic factors. For example, L2 learners are faster at reading sentences where the ambiguous NP is not a plausible direct object for the initial verb (2b) in comparison to those with a plausible direct object (2a) (as reported in Roberts & Felser, 2011; see also Williams, 2006; Dussias & Cramer Scaltz, 2008).

- (2) a. The journalist read the book had amazed the judges.
- b. The journalist read the girl had amazed the judges.

L2 learners, therefore, can process the input incrementally. However, their moment-by-moment processing has in some cases been found to differ from that of native speakers, in particular where the learners' L1 has an influence. For instance, Frenck-Mestre and Pynthe (1997) found that English learners of French hesitated when reading in their L2 intransitive verbs like *obéir*—in English *obey* is optionally transitive—which suggests a direct influence of the subcategorization properties of learners' L1 on their processing of the L2. Even more subtle or indirect L1 influences on L2 learners' real-time comprehension of garden-path constructions has also been observed, such as whether a learner's L1 has grammaticalized aspect or not (Roberts & Liszka, 2008).

Despite these L1 influence findings, there are many studies in which a learner's L1 has been found to have no effect whatsoever, even when (a) in paper-and-pencil tasks learners perform like native speakers, and (b) the learners could in principle transfer linguistic knowledge from their L1. For instance, Havik, Roberts, van Hout, Schreuder, and Haverkort (2009) reported that in an offline measure, German L2 learners of Dutch preferred the subject-first word order when reading temporarily ambiguous subject-relative ([3a] below) and object-relative clause (3b) constructions. This subject-first preference is often observed in native speakers of flexible word-order languages, and, critically for this study, had been reported for native speakers of both German and Dutch. However, the German L2 learners' subject-first preference in the Havik et al. study was not reflected in their real-time sentence comprehension. Specifically, they did not slow down when the number information on the auxiliary verb forced an object-first interpretation (3b), unlike native speakers of both Dutch and their L1, German, with comparable constructions.

- (3) a. Daar is de machinist die de conducteurs heeft bevrijd uit het treinstel.
There is the driver who the conductors has freed from the carriage.
'There is the train driver who has freed the conductors from the carriage.'
- b. Daar is de machinist die de conducteurs hebben bevrijd uit het treinstel.
There is the driver who the conductors have freed from the carriage.
'There is the train driver who the conductors have freed from the carriage.'

Given the results reported earlier showing that L2 learners can assign grammatical roles during online comprehension, the question arises as to why the German learners in this study did not appear to find object-first relative clause constructions comparably difficult to process, despite the strong similarity between Dutch and their L1, German. The authors argue that incremental processing may indeed occur in L2 processing, but only when there is enough lexical-semantic (or meaning) information in the input. In other words, L2 learners may postpone making online commitments to an analysis in the absence of lexical-semantic information. Given that in (3) both the NPs are animate and therefore

equally semantically able to be subjects or objects, in this case the learners were not garden-pathed. In other words, they were not committed to an analysis and so they were not surprised by incompatible subsequent material in the input, even though the constructions under investigation are maximally comparable between the L1 and the L2 (for strikingly similar findings, see also Papadopoulou & Clahsen, 2003).

Support for this conclusion was found in the results of a comparable self-paced reading study (Jackson & Roberts, 2010). German L2 learners of Dutch read sentences like (4), which differed from those in (3) in that one of the two ambiguous NPs was animate (*de clown* ‘the clown’) and the other inanimate (*de taarten* ‘the pies’). Unlike those in the Havik et al. (2009) study, the German L2 learners performed like native Dutch speakers, and showed evidence of an online preference for subject-first constructions. That is, they were quicker to read the sentences which forced a subject-first in comparison to an object-first reading, indicating that they assigned a subject grammatical role to the animate NP, and did so during their online processing. Thus in contrast to those in the Havik et al. study, the L2 learners showed evidence of having an expectation for either a subject- or an object-first analysis (created on the basis of lexical-semantic cues which were absent in the Havik et al. materials, such as *subject is likely to be animate*, *object is likely to be inanimate*), and these incremental analyses were either confirmed or disconfirmed when the readers encountered the disambiguating auxiliary verb later in the input.

- (4) Voor de kinderen is de clown die de taarten heeft gegoooid het hoogtepunt
 For the children is the clown who the pies has thrown the highlight
 van de voorstelling.
 of the performance.
 ‘For the children the clown who threw the pies was the highlight of the performance.’

In sum, L2 learners appear to be native-like in their ability to incrementally process such sentences, assigning grammatical roles during real-time comprehension, and rapidly accessing and applying semantic (e.g., plausibility and subcategorization) information to their ongoing analyses of the input. However, the results reported above suggest that incremental processing may occur only in the presence of enough lexical-semantic information: In its absence, analyses may be suspended. Suspending online commitments to analyses could indeed be a sensible strategy, given that L2 learners appear to have more difficulty in recovering from initial misanalysis than native speakers in general (see, e.g., Roberts & Felser, 2011).

Processing Dependencies

As well as focusing on ambiguities, L2 processing researchers have also been interested in learners’ processing of syntactic dependencies; in other words, how links are established between elements within or between sentences. For example, in order to interpret a sentence like that in (5), the fronted element *which book* must be linked to the verb that appears later in the sentence, *wrote*. In (6), the pronoun *he* has little meaning until it is linked to a lexical NP earlier in the discourse, *John*. In processing terms, establishing dependencies between elements in real time is of interest because the process entails that the comprehender must hold certain information in memory (*which book* in [5] and *John* in [6]) while incrementally processing the input, and then, at the correct point later on (at or immediately after *wrote* in [5] and *he* in [6]), the link must be established, where all the relevant information is integrated such that full interpretation of the utterance can take place.

- (5) *Which book_i did you say Fred wrote e_i?*
 (6) *John_i told Sally_j how he_i had got a new job.*

Although it has been demonstrated that L2 learners can establish dependencies among constituents during real-time processing, the results from some studies suggest that they may not do so in a manner identical to that of native speakers. Specifically, some research has found that even very advanced L2 learners may not make use of purported syntactic “gaps” (the position from which a constituent has moved, e.g., following *wrote* in [5], marked *e_i*) during the real-time establishment of dependencies in complex constructions. For example, Marinis, Roberts, Felser, and Clahsen (2005) reported that for native English speakers, integrating the moved object *the nurse* with the embedded verb *angered* in (7a) was facilitated by the availability of an intermediate syntactic gap at the clause boundary (*e_i'*), compared to sentences of the same length that did not contain an intermediate gap (7b).

- (7) a. The nurse [_{CP} who_i the doctor argued [_{CP} e_i' that the rude patient had angered e_i]]
 is refusing to work late.
 b. The nurse [_{CP} who_i the doctor's argument about the rude patient had angered e_i]
 is refusing to work late.

In other words, for the native English speakers, reading the verb *had angered* was faster in (7a) than in (7b).

This suggests that the comprehenders activated the fronted constituent at this grammatically determined position, which “refreshed” it in memory midway through the sentence, and in turn made it more activated, and thus more easily available for integration with the verb in (7a) in comparison to (7b). However, the advanced L2 learners of English—even those in whose L1 relative clause constructions are formed in the same way (Greek, German vs. Japanese, Chinese)—were not faster to read the verb *had angered* in (7a) than in (7b). Critically, this was the case even though they had no trouble comprehending the sentences. Marinis et al. (2005) argue that the dependency between the fronted constituent (*the nurse*) was integrated with the subcategorizing verb (*had angered*), but that no use was made by the L2 learners of any structurally determined intermediate position.

As stated above, the L2 learners performed like each other, and differently from the native speakers of English, irrespective of whether relative clause constructions worked in a comparable way in their L1 to that in English. It was on the basis of these and similar findings in L2 processing (e.g., Felser & Roberts, 2007), together with the observed lack of L1 influence in the absence of lexical-semantic information, that Clahsen and Felser (2006) proposed the Shallow Structure Hypothesis for L2 processing. This hypothesis claims that L2 learners' mental representations are less grammatically detailed and more semantically/lexically driven than those of native speakers. There is some debate on the matter, though, with some researchers arguing that L2 learners would in fact show parallel effects to those of native speakers with sentences like (7) if given enough time (see e.g., Dekydtspotter, Schwartz, & Sprouse, 2006), and arguing that L2 learners are therefore quantitatively rather than qualitatively different from native speakers.

It may be that observed L1–L2 processing differences are found only for such structurally very complex sentences. Using eye-tracking, Roberts, Gullberg, and Indefrey (2008) investigated whether German and Turkish L2 learners of Dutch would process subject pronouns in texts (as in [8] below) in the same way as Dutch native speakers. Such *pronoun resolution* or *co-reference* involves establishing a dependency between elements: The pronoun (*hij* in [8]) must be linked to a referent (or *antecedent*) in the earlier discourse. There might

be only one referent (grammatically) available for the pronouns, as in (8a) where the masculine singular pronoun *hij* can co-refer only with the referent *Peter*. However, often there are ambiguous contexts, where more than one referent can potentially co-refer with the pronoun, as in (8b) (*Peter* and *Hans*), and where the comprehender must draw on information from various sources (syntactic, pragmatic, information structural, etc.) to establish the link between the pronoun and its referent.

- (8) a. De Werknemers zitten in het kantoor. Terwijl Peter_i aan het werk is, eet hij_i een boterham.
 'The workers are in the office. While Peter_i is working, he_i is eating a sandwich.'
 b. Peter_i en Hans zitten in het kantoor. Terwijl Peter_i aan het werk is, eet hij_i een boterham.
 'Peter_i and Hans are in the office. While Peter_i is working, he_i is eating a sandwich.'

When Roberts et al. elicited the learners' interpretation for the ambiguous pronoun (e.g., [8b]) during a paper-and-pencil task, an effect of the L2 learners' L1 was evident: When asked for their preferred referent for the subject pronoun the German L2 learners patterned with the Dutch native speakers, overwhelmingly choosing the most recent, sentence-internal referent for the pronoun (*Peter*; Dutch 100%, German L2 learners 91%), whereas the Turkish learners chose this referent only 55% of the time. Under an L1-influence account, these findings are predicted. That is, German and Dutch subject pronouns work similarly, and both differently from Turkish. In Turkish (a so-called *null subject* language), to achieve co-reference with the most recent, and therefore psychologically available, referent *Peter*, no subject pronoun would be used, as illustrated in (9a). This is the default case. Use of an overt pronoun (e.g., *o* 'he/she') is marked, and thus signals the non-default interpretation: in (9b); this means co-reference not with the most recent referent, *Peter*, but with the non-local referent *Hans*. A similar interpretation can be obtained in the Dutch example (8b) by placing stress on the pronoun *hij*.

- (9) a. Peter_i ve Hans ofiste oturuyorlar. Peter_i çalışırken, —_i sandviç yiyor.
 Peter and Hans office sit-PL. Peter work, sandwich eat.
 'Peter and Hans are in the office. While Peter is working, he is eating a sandwich.'
 b. Peter_i ve Hans_i ofiste oturuyorlar. Peter_i çalışırken, o_i sandviç yiyor.
 Peter and Hans office sit-PL. Peter work, he sandwich eat.
 'Peter and Hans are in the office. While Peter is working, **he** is eating a sandwich.'

Despite the L1 influence observed in the offline data, unexpectedly, during real-time comprehension the L2 learners patterned together, and differently from the native Dutch speakers. Both the German and the Turkish learners took longer to process the pronoun *hij* in the ambiguous (8b) than in the unambiguous context (8a). What can account for the difference between the results of the tasks? The authors argue that since pronoun resolution in general involves computing and integrating grammatical and discourse-pragmatic information at the same time, it is this integration of information from multiple sources during real-time comprehension that is more problematic for L2 learners than for native speakers, and so causes processing slow-downs. This appears to be the case even when the L1 and the L2 are typologically closely related (German, Dutch), and irrespective of a comprehender's final interpretation for the pronoun.

In sum, the results from the studies on dependency processing suggest that L2 learners may have trouble integrating, during real-time comprehension, grammatical information with information from other sources.

Processing Ungrammatical Sentences in the L2

Another topic that has recently been focused on in L2 processing is that of L2 learners' sensitivity to the (un)grammaticality of the L2 input: assessing what is and what is not grammatical in a learner's current *interlanguage*, and thus, obtaining a picture of what a learner knows about the L2 (Schimke, 2009). Researchers from a formal (*universal grammar*, UG) perspective focus on the observed difference in ultimate attainment between L1 and L2 learners. Debate in this research framework centers on the properties of learners' underlying grammar, in particular in the context of discussions on the presence or absence and development of functional projections, which in turn inform debates on whether or not learners have access to the principles and parameters of UG.

Some researchers claim that the observed optionality in the production of target-like morphology that is very often characteristic of L2 learners reflects a problem that lies at the level of grammatical representations: Learners have a "representational deficit," and are unable to acquire L2 forms unless these are present in the L1 (e.g., Hawkins, 2005). Others claim that learners of any L1 background can acquire these L2 forms, and so the difficulty rather lies with *accessing* them: a processing/accessibility problem (e.g., Prévost & White, 2000), and this predicts difficulty during real-time processing. Traditionally, researchers have studied learners' production and elicited their grammaticality judgments, and therefore they have had to infer from explicit, often metalinguistic data what may underlie L2 learners' difficulty with the TL. More recently, greater use has been made of more implicit, online processing techniques to gain a picture of learners' underlying grammar, and therefore such processing studies can add critical data to current debates in L2 acquisition (e.g., Hopp, 2009).

Conclusion

To conclude, even though learners may show the same patterns of interpretation as those of native speakers in tasks that measure ultimate interpretation, they may have arrived by a different route: Thus investigating how L2 learners process the TL in real time can inform us of the nature of the human sentence processing mechanism in general. Furthermore, using converging methods in the study of L2 acquisition gives a more detailed and rounded picture of what a learner *knows* about the TL, given that proficiency involves the acquisition of knowledge and ability to put it to use in real-time processing.

Sentence Production in a Second Language

JUDIT KORMOS

The Basic Architecture of L2 Sentence Production

Sentence production has four important components: (a) *conceptualization*, that is, planning what one wants to say; (b) *formulation*, which includes the grammatical, lexical, and phonological encoding of the sentence; (c) *articulation*, in other words, the production of speech sounds; and (d) *self-monitoring*, which involves checking the correctness and appropriateness of the produced output (Levelt, 1989). In L1 (first language) production, planning the message requires attention, whereas formulation and articulation are automatic. Automatic processing mechanisms can work in parallel, which makes L1 speech generally smooth and fast. In the case of a second language (L2), however, formulation and articulation are often insufficiently automatized and require conscious attention, which hinder parallel processing and might make the speech of nonproficient L2 learners appear slow and hesitant.

In Levelt's (1989) model, which was originally devised to account for L1 speech production, there are three knowledge stores: the store for the knowledge of the external and internal world (*semantic memory*), the *mental lexicon*, and the *syllabary*. Semantic memory contains linguistic and nonlinguistic concepts as well as meaning-related memory traces associated with these concepts. The mental lexicon has two levels: a *lemma* and a *lexeme* level. The lemma contains syntactic and the lexeme level morphophonological information related to lexical items (Levelt, 1989). The syllabary stores the automatized gestural scores used to produce syllables. Based on empirical findings in L2 speech production research, it can be hypothesized that all these knowledge stores are shared between L1 and L2 (de Bot, 1992; Kormos, 2006). In L2 production, however, an additional L2-specific knowledge store might be needed: the declarative memory of syntactic, morphological, and phonological rules in L2. In L1 production, these rules are assumed to be automatized and to be part of the encoding systems (Levelt, 1989). For bilingual speakers, however, many of the phrase- and clause-building as well as phonological rules are not automatic and are stored in the form of declarative knowledge. Ullman (2001) cites several pieces of evidence from neuroimaging research that declarative knowledge concerning grammar is stored in a brain region distinct from the area which is responsible for the processing of automatized rules.

One of the basic mechanisms involved in producing speech is *spreading activation*. Spreading activation is a metaphor adapted from brain research, which is based on the finding of neurological studies that neural networks consist of interconnected cells (neurons) that exchange simple signals called activations via the connections they have with each other (Hebb, 1949). The speech processing system is assumed to consist of hierarchical levels (conceptualization, formulation, articulation), among which information is transmitted through activation spreading, and of knowledge stores such as the lexicon, within which activation can also spread from one item to related items. Decisions are made on the basis of the activation levels of the so-called *nodes* that represent various units such as concepts, word forms, phonemes, and so forth. The node of the required category which has the

highest level of activation is accessed. Immediately after this node is selected, it spreads its activation further to the lower-level nodes.

Encoding Second Language Speech

Sentence production in L2 speech starts with conceptualizing the message, which involves the activation of the relevant concepts to be encoded and deciding on the language in which the message will be conveyed. The output of the conceptualization process is the *preverbal plan*, which contains the conceptual specifications for the message. L1 and L2 concepts are assumed to be stored together in the semantic memory (Francis, 2005) and can be identical, shared, or rarely completely separate. The extent to which L1 and L2 concepts are shared depends on the concept (e.g., concepts expressed by concrete nouns tend to be shared, while those expressed by abstract nouns show partial overlap), the situation in which the L2 was acquired (e.g., if the two languages were learned and are used in different environments, concepts might be separate) and the speaker's level of proficiency (e.g., at the beginning level L2 concepts are completely mapped on L1 concepts, whereas at advanced levels the L2 conceptual representation is greatly enriched) (de Groot, 1992).

In the first phase of *conceptual preparation* the message is generated through *macro planning* and *micro planning*. Macro planning involves the elaboration of the communicative intention. Communicative intentions are expressed by *speech acts*, which are actions one performs by speaking such as informing, directing, requesting, apologizing, and so forth (Austin, 1962). In order to perform a speech act one needs to select the information to be encoded and decide on the order in which this information will be conveyed. Once these decisions have been made, micro planning can start. In micro planning speakers decide on the perspective that they need to take in conveying the message (e.g., whether they would say "The dog is chasing the cat" or "The cat is chased by the dog"). At this stage speakers also consider whether an object, a person, or a situation has already been mentioned in previous discourse. This influences decisions such as whether a noun or phrase or a pronoun (e.g., "the father" or "he") should be used. Similar decisions concerning what constitutes new and old information are also made in the micro-planning stage. In addition, micro planning involves giving propositional content to the message, such as specifying the referents and the argument structure of the message, as well as assigning thematic roles (e.g., who is the experiencer or patient of actions), specifying the referents (i.e., quantifying, describing, or both quantifying and describing it) and the mood of the message (e.g., declarative, interrogative, imperative, etc.) (Levelt, 1989). The micro plan also contains language-specific information, for example, the selection of the appropriate tense in the language one speaks. The outcome of the macro- and micro-planning processes is the *preverbal plan*. As the name suggests, this preverbal plan is not yet linguistic although it is linguistically accessible, that is, it is assumed to contain all the necessary information to convert meaning into language.

The language of the message also needs to be set in the conceptualization phase. Language choice is dependent on sociolinguistic factors such as the nature of the communicative situation, relationship of the interlocutors, prestige of the languages involved, and so forth. In most bilingual speech production models language choice is indicated in the form of a *language cue*, which is added to the activated conceptual information (e.g., de Bot, 1992; Kormos, 2006). The language cue is attached to each concept separately, and therefore it is possible that in the case of encoding a sentence, a preverbal plan consists of a string of activated concepts to which different language cues are added. Conceptualization, especially the micro-planning stage, is greatly influenced by the language to be used in communication. Different languages categorize events and concepts in different ways, which affects

the encoding of motion, spatial relations, time, as well as global discourse structure (Slobin, 1996). As a consequence, during micro planning speakers have to select language-specific conceptual features and need to tailor their message in a way that is encodable in the selected language.

Remaining still at the phase of conceptualization, we also need to consider the problem that not every instance of language is creatively constructed. In fact, the majority of our utterances are combinations of memorized phrases, clauses, and sentences, which together are called formulaic language (Pawley & Syder, 1983). In order to account for the use of formulae, one possibility is to assume that chunking—the creation of larger production units—is done at the level of the conceptualizer. In other words, it might be postulated that for expressing various communicative functions such as requesting, apologizing, expressing surprise, and so forth, speakers have conceptual chunks consisting of a group of concepts, which they activate as one unit when routinely expressing certain communicative intentions. These conceptual chunks spread activation to the corresponding linguistic chunks, which are also stored and retrieved as one unit (i.e., one lemma). An alternative mechanism for encoding formulaic language is proposed by Pickering and Garrod (2004), who regard formulaic language as evidence against the linear nature of speech production. They argue that in certain cases, “people might short-circuit parts of the production process” (p. 181) and speakers might not always implement every stage of speech production.

In most models of speech production (e.g., Levelt, 1989, Dell & Juliano, 1996), it is assumed that not only the concept that the speakers want to encode is activated, but semantically related concepts also receive activation. For example, in the case of the concept of DOG related concepts, such as CAT, WALK, BONE, and so forth, also become active. When bilingual speakers use one of their languages, the concepts in the other language will also be activated to some extent. Only the intended concept in the selected language is chosen for further processing (e.g., Levelt, 1989).

In bilingual speech production models, lexical encoding means the matching of the conceptual specifications and the language cue with the appropriate lexical entry in the mental lexicon. The conceptual specifications send activation both to L1 and L2 lemmas (Hermans, Bongaerts, de Bot, & Schreuder, 1998; Costa, Caramazza, & Sebastián-Gallés, 2000) and they both compete for selection (Hermans et al., 1998; Lee & Williams, 2001). The winner of the competition is the lemma whose features match all the conceptual specifications including the language cue (Poulisse & Bongaerts, 1994). The mental lexicon contains L1 and L2 lemmas and lexemes; in other words, it is a depository of a speaker’s knowledge of word forms (lexemes) and their syntactic and morphological features (lemmas). Just as the conceptual system, the lexicon is conceived of as a network in which entries have connections with each other. Connections might exist between L1 and L2 lemmas and lexemes, and between items within languages. Well known and frequently used L2 entries occupy a central position in the network and have a high number of links with other items, whereas words not known very well by L2 speakers can be found at the periphery of the network (Wilks & Meara, 2002). The strength of connections might also vary, at the beginning of the learning process links between L1 and L2 items might be stronger than links among L2 lexical entries (Kroll & Stewart, 1994).

Syntactic encoding in speech production entails two important procedures. First, syntactic information related to a lexical item such as gender in languages like Italian or German, countability status (i.e., whether a noun is countable or not), and optional and obligatory complements of verbs are activated. Next, syntactic encoding mechanisms are triggered, which assemble phrases and clauses using the activated words and their syntactic features. For example, in the case of the verb “enter” the information concerning optional complements is activated, and a verb-phrase building procedure is initiated, which encodes the object such as “the room.” It is hypothesized that for balanced bilinguals L2

lemmas point to syntactic information that is specific for the given L2 entry, while for lower-level learners L2 lemmas might be associated with the syntactic information of the corresponding L1 item. This is supported by the frequent occurrence of transfer errors, when syntactic information concerning particular words is transferred from L1. This processing stage draws on declarative knowledge stored in the mental lexicon. The next major phase involves phrase and clause structure building, aligning grammatical information across phrases (e.g., subject–verb agreement) and arranging phrases in the appropriate order. At this stage L1 speakers and balanced bilinguals use procedural knowledge of syntactic and morphological rules of the language, which are automatically applied. L2 learners at lower levels of proficiency might proceed in several ways. First of all, some of the rules might be acquired already in the form of procedural knowledge, while other rules might be stored in declarative memory and used consciously. It is also possible that some rules are not acquired at all. In this case some kind of communication strategy is used, which might be the conscious transfer of the rule from L1, or simply juxtaposing the lexically encoded concepts after each other to express the intended message.

L1 and L2 syntactic encoding procedures might interact in a number of ways. As already mentioned, L1 syntactic information and encoding procedures might be transferred to the L2. In addition, L1 syntactic encoding procedures can influence the likelihood with which L2 procedures that are similar to the ones in the learners' L1 are used (Meijer & Fox Tree, 2003).

The next phase of processing is phonological encoding, which involves the activation of the phonological form of the word to be encoded, syllabification and setting the parameters for the loudness, pitch, and duration of intonational phrases consisting of several words. At this stage again, the basic mechanisms of phonological encoding are similar in L1 and L2 production. As far as the activation of phonological word forms in L2 processing is concerned, it is assumed that the phonological form of nonselected lemmas can also be activated, which means that both L1 and L2 lexemes compete for selection in bilingual phonological encoding (Costa et al., 2000). As a next step, phonological word forms activate the phonemes of the word in serial fashion, starting from the first phoneme and ending with the last one (Roelofs, 1999). Phonemes are stored and retrieved as one unit such as [b] and not as a list of features such as [+voiced] [+labial] [–nasal] (Roelofs, 1999). L1 and L2 phonemes are stored in a single network (Poulish, 1999) within the lexicon at the lexeme level, and memory representations for phonemes that are identical in L1 and L2 are shared (Roelofs, 2003). Once acquired, phonemes that are different in L1 and L2 are stored as separate representations. At the beginning of the acquisition process, however, L2 specific phonemes are frequently equated with an L1 phoneme that is similar to the target phoneme (Flege, 1987). In the case of balanced bilinguals, syllabification and metrical encoding proceeds in the same way. Similarly to the processes of syntactic encoding, L2 learners at lower levels might need to resort to the declarative knowledge of lexical and postlexical phonological rules or, in the lack of it, transfer these rules from their L1.

In phonetic encoding, articulatory gestures for syllables are retrieved. Syllable programs for L1 and L2 are stored together in the syllabary. Beginning L2 speakers mostly rely on L1 syllable programs, whereas advanced L2 speakers usually succeed in creating separate chunks for L2 syllables (de Bot, 1992).

The final process of speech production is monitoring, which proceeds in a similar way in both L1 and L2 production. In order to avoid the necessity of duplicating knowledge, Levelt (1989) assumed that the same lexicon is used for both production and perception, and the same speech comprehension system attends to one's own speech and to other speakers' utterances (via the acoustic-phonetic processing module). Furthermore, the interpretation of the perceived messages is carried out by the same conceptualizing module as the one in charge of generating one's own messages. In Levelt's system of speech processing

there are three monitor loops (i.e., direct feedback channels leading back to the monitor) for inspecting the outcome of the production processes. The first loop involves the comparison of the preverbal plan with the original intentions of the speaker before being sent to the formulator. In this phase the preverbal plan might need modification because the speaker finds that the formulated message is not appropriate in terms of its information content or is not acceptable in the given communicative situation. The second loop concerns the monitoring of the phonetic plan (i.e., “internal speech”) before articulation, which is also called “covert monitoring” (see also Postma & Kolk, 1993). In simple terms this means that in certain cases the speaker notices an encoding error such as an erroneously selected word before it is actually uttered. Finally, the generated utterance is also checked after articulation, which constitutes the final, external loop of monitoring, involving the acoustic-phonetic processor. Upon perceiving an error in the output in any of these three loops of control, the monitor issues an alarm signal, which, in turn, triggers the production mechanism for a second time.

Speaker–Hearer Interaction in Speech Production

The encoding mechanism presented above considered the speaker in isolation engaged in a monologue. Speech production, however, usually involves at least two interlocutors who interact with each other in a dialogue. Psycholinguistic models of speech production rarely consider the speaker–hearer interaction and if they do, it is mainly with regard to how speakers take the context of speaking into account when formulating their utterances. In Levelt’s (1989) model it is the so-called situation model, which holds information on what had been said earlier in the interaction. The situation model is assumed to guide the macro-planning phase of speech production. In a dialogue, which is a joint activity, it is evident that the situation models of the listener and the hearer interact.

The question is how the interaction of the situation models takes place. Pickering and Garrod (2004) propose that the basic process responsible for explaining successful communication between interlocutors is *alignment*. This means that in order to understand each other, the speaker’s and listener’s situation model needs to be coordinated, in other words, they need to have a shared representation of the context of the conversation. The basic tenet of Pickering and Garrod’s model of the dialogue is that it is not only the situation model that needs to be aligned between the interlocutors but also lower levels of linguistic representations (i.e., lexical and semantic representation). They further argue that alignment is automatic and proceeds through priming, that is, the “activation of a representation in one interlocutor leads to the activation of the matching representation in the other interlocutor directly” (p. 177). This mechanism explains why people tend to use similar words, expressions, and linguistic structures to the ones produced by their interlocutors.

Shohamy, Elana

KENDALL A. KING

Elana Shohamy is an internationally recognized scholar in the study of language testing, language policy, immigration, and linguistic landscapes. Her research, writing, teaching, and consulting work over the last three decades have advanced our understanding of how language, testing, and public policy interact to produce differences in educational access and achievement across groups, as well as the roles of these forces in the negotiation of power and identity within multilingual societies such as Israel and the United States.

Shohamy's earliest writing and research investigated the measurement of second/foreign language speaking proficiency and reading (Seliger & Shohamy, 1989) with emphases on the biases of various testing methods (Shohamy, 1982). In subsequent decades, her work addressed a wide range of language assessment issues including alternative assessment, oral testing, classroom and diagnostic assessment, and "washback," with a focus on the social and political dimensions of language tests (e.g., Shohamy, 1994, 1995a, 1995b, 1996, 1997, 1998a, 2001a; Shohamy & Hornberger, 2007). Shohamy's best known contribution in this area concerns the power and misuses of tests; she examined how language tests are used by central authorities as tools to implicitly and covertly impact teaching, learning, and de facto language policies. Shohamy documented the negative consequences of tests in contexts of second language learning, migration, and, more recently, in the global phenomenon of language tests for citizenship (e.g., 1998b, 1998c, 2001b, 2008, 2009; Shohamy & Hornberger, 2007; Shohamy & Kanza, 2009). Her work in these areas, and in particular her leading role in bringing an ethical, humane, and political dimension to the largely psychometrically oriented field of language testing, were recognized by the International Language Testing Association with the Lifetime Achievement Award granted at the Language Testing Research Colloquium in April, 2010 at Cambridge University, England. Shohamy's current testing work draws attention to the need for more just and inclusive assessment procedures such as multilingual, multicultural tests that recognize and incorporate students' knowledge and skills.

Shohamy has extended this critical examination of language testing into the area of language policy. She was instrumental in the introduction of a new multilingual language policy in the Israeli educational system and has written widely on dimensions of Israeli language policy, such as the learning of spoken Arabic, the need to use Arabic as a medium of instruction at universities, and the cultivation of home languages (e.g., Spolsky & Shohamy, 1999). Her book, *Language Policy: Hidden Agendas and New Approaches* (2006) introduced an expanded language policy framework that illustrated how everyday, often invisible mechanisms (e.g., tests, workplace regulations, linguistic landscapes) create de facto language policies. These implicit policies, Shohamy argues, lead to inequalities, violation of individual human rights, suppression of diversity, and marginalization of both individuals and groups. Her recent work draws from archival, historical, and biographical research to document the hidden costs to individuals of Hebrew-only ideology as part of Hebrew revitalization and the concomitant suppression of home languages such as Yiddish (Shohamy, 2008). She was a founding editor—and currently serves as an editor—of the international, peer-reviewed journal *Language Policy*.

Most recently, Shohamy has been instrumental in the development of the field of "linguistic landscape" (Ben Rafael, Shohamy, Amara, & Trumper-Hecht, 2006), cohosting

an international conference and coediting two books on the topic (Shohamy & Gorter, 2009; Shohamy, Ben Rafael, & Barni, 2010). The study of linguistic landscape, broadly interpreted as the analysis of language (both written and visual) in public space and the messages it delivers in terms of policy, power relations, ethnicity, and education, is quickly becoming a major focus of sociolinguistics, attracting myriad theoretical and methodological approaches and holding clear practical and political implications. Her most recent projects focus on the ideologies delivered via the linguistic landscape in the city of Tel Aviv and on how Arabic is constructed as a minority language despite its wide use within communities in Israel.

Shohamy has held visiting research and teaching positions around the world, including at the University of California, Berkeley, Georgetown University, Hong Kong Institute of Education, Pennsylvania State University, and the University of Toronto. She is currently Professor of Language Education, and Chair of the Language Education Program at Tel Aviv University. In addition to her lifelong fascination with language, identity, justice, and urban entities, she is passionate about bike riding, photography, and people, including, but not limited to, her two granddaughters, Alma and Liya.

Shuy, Roger

PHILIP GAINES

Roger W. Shuy (1931–) is an American linguist with specializations in dialectology, discourse analysis, sociolinguistics, and forensic linguistics. Shuy was an important figure in the formation and development of the field of applied linguistics, having cofounded the American Association of Applied Linguistics, who honored him in 1999 with the Award for Distinguished Scholarship and Service. He also cofounded the association New Ways of Analyzing Variation (NWAVE) and served on the editorial board of *TESOL Quarterly*. Shuy is perhaps best known for his many books and articles on the relationship of language and the law.

Shuy received his BA in English at Wheaton College in 1952 and his MA from Kent State University. While working on his PhD at Case Western Reserve University, a course in Middle English sparked the interest in English language studies that would define his academic career. Under the dialectology mentorship of Raven McDonald, Shuy completed his dissertation in 1962 on the Northern–Midland dialect boundary in Illinois. While doing his doctoral work at Case, Shuy first taught high school English and then accepted a position teaching linguistics at Wheaton College, counting among his students Walt Wolfram and Ralph Fasold, both of whom later became important scholars in sociolinguistics. Shuy subsequently taught at Michigan State, where he helped found the MSU linguistics department, at the same time conducting a pioneering Detroit dialect study.

A turning point in Shuy's theoretical and methodological approach to language variation occurred at the Linguistic Society of America Summer Institute at Indiana University in 1967, where he was influenced by the wide-ranging sociolinguistics work of William Labov and John Gumperz. Shuy subsequently was appointed director of sociolinguistic research at the Center for Applied Linguistics in Washington, DC, a private nonprofit organization founded by Charles Ferguson. While at CAL, Shuy was asked by the dean of the School of Languages and Linguistics at nearby Georgetown University to design, develop, and direct a new sociolinguistics PhD program there. He agreed, and in anticipation of its opening in 1969, the program recruited nationally and internationally for high-achieving students, many of whom have since gone on to distinguished careers in sociolinguistics.

Following a chance encounter in 1979 with an attorney who enlisted his help in a criminal law case involving language as the major evidence, Shuy began to focus on forensic linguistics, working on a wide range of case types but with a particular emphasis on criminal cases. Shuy was appointed chair of linguistics at Georgetown in 1988, where he continued to teach and research until his retirement in 1996 as distinguished professor of linguistics emeritus. He was later inducted as a fellow of the Linguistic Society of America. Following his retirement from Georgetown, Shuy relocated to Montana to continue consulting and lecturing on forensic linguistics. In 2009, Shuy was chosen as editor of the *Oxford Studies in Language and Law* series, published by Oxford University Press.

Shuy's work in forensic linguistics emerged from substantial scholarship in language studies. His early focus was American dialectology, with an emphasis on social dialects and urban language. Representative works include *Social Dialects and Language Learning* (1965) and *Discovering American Dialects* (1967). During this time, Shuy also brought his scholarly interests to bear on applied linguistic matters with the publication of books and articles on teaching and learning Standard English, bilingualism, literacy, and medical

communication. Shuy's attention to language variation continued well into the 1970s, making significant contributions to the emerging general field of sociolinguistics, coediting a series of collections published by Georgetown University Press on issues, research, and trends in sociolinguistics, particularly from a cross-disciplinary perspective. The emphasis of Shuy's scholarly work is best identified as applied sociolinguistics, which, according to Suzanne Romaine (1994, p. vii), "deals with the social and political implications of fundamental inequalities in language use in various areas of public life, e.g. school, courts, etc." Shuy's primary interest has always been to bring current linguistic theory to bear on real-life language events.

In the late 1970s and early 1980s came Shuy's turn to the study of the interface of linguistics and law, which later became commonly referred to as forensic linguistics. For Shuy, the starting point for the analysis of language in legal contexts has always been linguistics: The researcher examines the text, whether written or spoken, through the lens of the core areas of linguistic description and analysis—phonetics, morphology, syntax, semantics, and so forth. The language under consideration may be susceptible to revealing analysis from multiple linguistic perspectives. Early representative journal articles by Shuy include discussions of the role of linguistic evidence in defense cases, topic analysis in criminal evidence, the linguistic analysis of tape recordings, comprehensibility in police interactions with suspects, and dialects as evidence in law cases. Other work focused on the linguistic analysis of warning labels, product liability, car sales discourse, the Miranda warning, and bilingual evidence. Shuy's recognized authority for the application of linguistics to legal matters is represented by the inclusion of his articles "Forensic Linguistics" in Aronoff and Rees-Miller's *The Handbook of Linguistics* (2000) and "Applied Linguistics in the Legal Arena" in Candlin and Sarangi's *Handbook of Communication in Organisations and Professions* (2011a).

Along with Malcolm Coulthard of the University of Birmingham, Shuy was largely responsible for the birth of forensic linguistics as a distinct subfield within applied linguistics. While the (probable) first extant scholarly use of the term "forensic linguistics" appeared in a 1968 article by Swedish linguist Jan Svartvik, it was not until the late 1970s that Shuy and other language scholars began vigorously exploring the implications of linguistic analysis for a range of texts—both spoken and written—at issue in legal and law enforcement contexts. While others in both linguistics and law had been studying the interface between linguistics and language use in legal contexts, Shuy demonstrated the extent and variety of potential approaches.

Perhaps the most significant scholarly contribution made by Shuy in forensic linguistics has been the range and detail of example analyses—and accompanying commentary—he has offered in a series of important scholarly monographs, beginning in 1993. In his first book in this series, *Language Crimes: The Use and Abuse of Language Evidence in the Courtroom* (1993), Shuy applied principles of speech act theory, conversation analysis, politeness theory, discourse analysis, and topic analysis to identify meaning and intentionality in police tape recordings of individuals suspected or accused of "language crimes" such as bribery, threats, and perjury. In *The Language of Confession, Interrogation, and Deception* (1998a), Shuy examined the form and style of the language of police interrogators and their suspects to determine the amount of manipulation performed by the questioners and the degree of deception/truthfulness of their respondents. *Bureaucratic Language in Government and Business* (1998b) explored problems of meaning and comprehensibility in a wide range of documents and forms used by both governmental and commercial entities, with an eye toward making such documents more transparent for consumers. In *Linguistic Battles in Trademark Disputes* (2002), Shuy demonstrated how virtually all the core areas of theoretical linguistics can be enlisted to help resolve legal conflicts in which claims to the ownership of words, phrases, and symbols are contested.

Shuy revisited the domain of law enforcement in *Creating Language Crimes: How Law Enforcement Uses (and Misuses) Language* (2005)—this time to analyze the language of undercover operatives and their suspect targets, using discourse and conversation analysis techniques to reveal the ways in which law enforcement personnel manipulate verbal interaction in order to create the appearance of guilt. In a break from his discussions of actual cases, Shuy wrote *Linguistics in the Courtroom: A Practical Guide* (2006), essentially an advice manual for new and prospective forensic linguists, based on his extensive experience in the linguistics analysis of language in evidence. *Fighting Over Words: Language and Civil Law Cases* (2008) was a scholarly foray into civil forensic linguistics in which he analyzed business contract disputes, deceptive trade practices, product liability, copyright infringement, discrimination, and trademarks. In *The Language of Defamation Cases* (2010), Shuy brought a panoply of linguistic techniques to bear in the analysis of allegedly libelous and slanderous language in a host of cases ranging from statements made in newspapers and on television to disputes involving religious leaders and entertainers. A similarly broad range of approaches characterizes *The Language of Perjury Cases* (2011b), in which Shuy shows the value of linguistic methodology for understanding how evidence is gathered and analyzed in prosecutions for perjury.

Signed Language Interpreting Profession

JEMINA NAPIER AND DELLA GOSWELL

Interpreting is an applied linguistic activity; the act of mediating between languages and cultures involves the application of linguistic knowledge across a wide range of communicative settings. Most interpreters work between two or more spoken languages, that is, within the same language modality; however, some interpreters work between two different language modalities. Signed language interpreters mediate communication between deaf and hearing people, across spoken and signed languages.

Signed language interpreters share the same values and aspirations as their spoken language counterparts in relation to norms of behavior (role), standards, ethics, professional associations, regulations, testing, and training. As with the broader interpreting field, signed language interpreting practice is diverse, with wide variation internationally in terms of stages of professionalization, provision of interpreter training, and certification.

Interpreting contexts can be split into two key domains, with different demands and relational features: “conference” interpreting and “community” interpreting. A major catalyst for the professionalization of spoken language interpreting was the requirement for large-scale simultaneous relay of testimony in multiple languages at the Nuremberg trials post-World War II (Baigorri-Jalón, 1999). This raised the profile of interpreting work, as well as the cognitive demands, and established the model and expectations of conference-style interpreting as the industry benchmark. The recognition of community interpreting (also referred to as liaison and public service interpreting) as an equally legitimate yet different style of interpreting work, where practitioners relate directly with clients in more interactive and varied settings, has come more recently (Hale, 2008).

In comparison, signed language interpreting (SLI) emerged from the community first; SLI practitioners were working with deaf people in medical, legal, and other dialogic settings long before they started working at conference level (Grbić & Pöllabauer, 2006). This entry gives an overview of the SLI profession with examples from around the world, including its development from Deaf community roots and the recognition of signed languages, the establishment of SLI associations and training, and the evolving concept of interpreter role. (A capital “D” is used to refer to the Deaf community as a collective who identify themselves as having a cultural and linguistic identity which is expressed by the use of a natural signed language. However, a lower-case “d” is used to refer generally to deaf persons as potential consumers of interpreting services, since not all of these individuals identify as culturally “Deaf,” even if they use a signed language in some form.)

Origins of the SLI Profession

The role of many children from immigrant families is akin to that of a “language broker” (Morales & Hanson, 2005), doing ad hoc interpreting from an early age for family members in a range of community settings. Thus, spoken language interpreters working in community settings are typically members of the same ethnic group as their clients (Gentile, Ozolins, & Vasilakakos, 1996). Most have grown up as bilingual (or multilingual) members

The Encyclopedia of Applied Linguistics, Edited by Carol A. Chapelle.

of the minority-language-speaking community, which engenders trust between interpreter and client (Edwards, Temple, & Alexander, 2005).

Similarly, hearing children who have deaf parents (often referred to as “children of deaf adults”—Codas) often undertake informal interpreting for their parents or other deaf family members (Preston, 1994). Therefore, many people who became the first generation of signed language interpreters grew up bilingually, using the local signed language at home with deaf family members, and the majority spoken/written language in all other communication outside the home (Bishop & Hicks, 2005); they either consciously or accidentally became interpreters. Although they are classified as native users of the signed language, bilingual Coda interpreters are not strictly members of the same minority-language/cultural group as their deaf parents, or deaf clients, because they can hear.

Prior to the professionalization of SLI, the role of “interpreter” for deaf people dealing with the mainstream was typically taken on by Codas, welfare and religious workers, and teachers at deaf schools (Napier, McKee, & Goswell, 2010). These early practitioners often had no formal linguistic or SLI training. Their “passport” into working with the Deaf community was their signed language skill and their intrinsic knowledge and understanding of the Deaf community.

A Paradigm Shift

Research on signed languages and Deaf communities has led to a paradigm shift in terms of who can become a signed language interpreter, and the overall status of the SLI profession. Deaf communities throughout the world have their own indigenous signed languages. Linguistic research has confirmed that these languages have their own grammar and lexicon and are not simply a manual representation of the surrounding spoken language. In fact, the research has established that signed languages are syntactically complex, with distinctive morphological, phonological, and sociolinguistic features.

It is now widely accepted that deaf people belong to a collective linguistic and cultural minority group and identify with one another by using the natural signed language of their country. The traditional medical perception of deaf signed language users as solely a disability group has therefore broadened to include a social model of deaf people as minority-language users (Ladd, 2003). Subsequently, many countries have formally recognized their signed languages as legitimate community languages in their own right. Signed languages are now routinely taught in a growing number of tertiary (postsecondary) institutions alongside spoken languages. Students can choose to learn to sign as a second language, a “foreign”-language study requirement, or because they aim to work with deaf people professionally. For example: as interpreters, educators for deaf children, social workers, speech-language therapists, or audiologists. In some countries, the national signed language is also taught in secondary schools as a foreign-language subject.

At the same time as emerging research legitimized signed languages, the adoption of human rights (race and disability) legislation in many countries from the 1980s and 1990s has reinforced the rights of linguistic minorities (including deaf people) in terms of access to education, employment, and services through accommodations such as interpreting. With formal language recognition and legal entitlement (i.e., funding), SLI provision has moved from a welfare base, to a viable profession, especially in developed Western countries such as Australia, Canada, Finland, the United Kingdom and United States of America. In many other countries, for example, Kosovo and Kenya, the SLI profession is still nascent (Napier, 2009).

Professionalization: Establishment of Professional Associations

Many of the foundation stones for the SLI profession were laid in the United States. In 1964, the Registry of Interpreters for the Deaf was established to create standards of practice for American sign language (ASL) interpreters, guidelines for the provision of interpreters, and regulation of interpreting quality and behavior via a code of ethics. The Conference of Interpreter Trainers (CIT) was subsequently established in 1979, with the goal of enabling information exchange between signed language interpreter educators and trainers in the USA, facilitated through a biennial convention. This process of constituting professional associations for signed language interpreter practitioners and trainers set the benchmark for other countries to follow. For example, professional SLI associations were established in Sweden in 1969, Canada in 1980, Finland and Scotland in 1982, England, Wales and Northern Ireland in 1987, Australia and Japan in 1991, Austria in 1998, and—more recently—Kosovo in 2006.

The SLI profession started developing a more international profile with the establishment of the European Forum of Sign Language Interpreters (EFSLI) in 1993 and the World Association of Sign Language Interpreters (WASLI) in 2003. Both of these umbrella associations are assisting in the connection and cohesion of signed language interpreters in different countries and at different stages of professional development.

Professionalization: Interpreter Role

Along with the establishment of SLI professional associations and training has come a shift in thinking around the role of the interpreter. The community beginnings of SLI, carried out by family, welfare workers, and missionaries, initially led to a perception of role often described as the *helper* model of interpreting (Pollitt, 1997). As SLI started to align with spoken language interpreting norms (based on conference interpreting models), and deaf people became more empowered with improved access to higher education, the helper model was eschewed in favor of a more detached and professional stance: the *conduit* model of interpreting (Pollitt, 1997). Other metaphors used for this more mechanistic approach included describing interpreters as telephones, bridges, or channels to communication (Roy, 1993).

Signed language interpreters in many countries adopted a code of ethics based on the experience and expectations of conference-style interpreting, where practitioners perform their work in a booth at the back of a conference venue, and do not interact with their consumers. For this type of interpreting work, the tenets of rigorous impartiality and interpreter neutrality are logical and realistic as conference interpreters are “disembodied voices”: heard but not seen by either side.

For signed language interpreters (in fact, any interpreters working in interactive community settings), the conduit approach of absolute impartiality and neutrality cannot be applied so strictly. Dialogic interaction, even within the same language and culture, can be messy—participants are not always eloquent, they make mistakes and can misunderstand each other’s intentions. When interpreters are added to the mix, they are often the only ones who can see the communication mismatches and repair linguistic or cultural misunderstandings. As a result, SLI practitioners working in community settings felt constrained by codes of ethics that implied their role was invisible, especially in assignments where intervention was clearly required to ensure effective communication between the parties.

SLI scholars (e.g., Roy, 1992) took the lead in debating the role of interpreters in community settings, and started addressing the complexity of interpreter-mediated interaction,

identifying the interpreter as a third party participant. The strictly conduit model for SLI practitioners working in these settings was therefore challenged, and has shifted to a *bilingual-bicultural* approach (Pollitt, 1997), where the interpreter is now seen to be responsible for making linguistic and cultural decisions and adjustments where appropriate. Spoken language interpreter perceptions of role also have moved in this direction, thanks to the work of scholars such as Wadensjö (1998), whose research showed that interpreters do actually participate in interpreted interaction, and Angelelli (2004), who clearly demonstrated that interpreters are not invisible players.

Professional Ethics

Many SLI associations initially adopted codes of ethics directly from their spoken language affiliates, which typically include adherence to the principles of confidentiality, impartiality, accuracy, and faithfulness in interpretation. Many of the original codes tended to adopt a proscriptive model that detailed what interpreters should not do. The re-definition of the interpreter role has generated further exploration of the concept of SLI professionalism and how to frame ethics that best support work in a community setting. Cokely (2000) proposed a more values-based code that represents the needs of all stakeholders: interpreters, deaf and hearing consumers, service providers, and paying clients. The Canadian SLI association was the first to update its code, reflecting Cokely's suggested approach, after extensive consultation with their Deaf community. The new code sets out core values to aspire to, rather than behaviors to avoid. The Australian SLI association subsequently adapted its code to reflect this model.

Compared with other minority-language users, and their spoken language interpreters, deaf consumers seem to have a strong vested interest in the workings of their allied SLI profession; perhaps because deaf people's usage of interpreters is more frequent, across more domains, and lasts for a lifetime. In countries where deaf people are professionally qualified and rely on interpreters in their workplace, their influence is critical—they are very clear about how they want to work with interpreters, what they need, and what they expect (Hauser & Hauser, 2008). As an acknowledgment of the close relationship between deaf consumers and signed language interpreters, WASLI has signed a joint agreement with the World Federation of the Deaf, to work in close partnership for the benefit of deaf people who use signed languages and the worldwide SLI profession.

Recently, deaf people have been recognized as having interpreting skills in their own right and are being employed as "deaf interpreters," often in situations where a deaf client has additional communication barriers and the "regular" hearing interpreter does not have the additional skills to manage alone. For example, where a deaf client uses idiosyncratic signs or gestures, sometimes unique to a family; uses a foreign signed language; has minimal or limited communication skills; is deaf-blind; uses signs particular to a given region, ethnic or age group; or is in a mental state that makes ordinary interpreted communication difficult (Napier et al., 2010). In these cases skilled deaf signers can bridge the gap, using innate linguistic and cultural knowledge of the Deaf community that most "hearing" interpreters cannot match. Deaf interpreters also work in conference settings, interpreting between two different signed languages (see Forestal, 2005, for further discussion of deaf interpreters).

Profile of Signed Language Interpreters

As a consequence of the linguistic, political, and social developments outlined in this entry, the population of signed language users and interpreters is changing. More people from "outside" the Deaf community are learning the language of the community, which in turn feeds into interpreter training programs. The typical interpreting student is now not a

native signer, but someone who has grown up in the mainstream spoken language community and has learned to sign as a second language. In addition, where deaf people have had access to higher education, they have raised the bar in terms of the skills needed for interpreting in tertiary education and professional work settings. These developments have had a major impact on the SLI profession, and in many countries, the increased demand for interpreters outstrips the supply.

The typical profile of signed language interpreters in Western countries with established SLI professions is as follows: female, young, white, second language (non-native) learners of a signed language, working part-time in community settings (e.g., medical, legal, education), and with increasing numbers having a university qualification, not necessarily in interpreting (Brien, Brown, & Collins, 2002; Napier & Barker, 2003). A female-dominated industry with part-time workers (and therefore low-income earners) has implications for the emergence of a fully fledged profession in the longer term.

The sociolinguistic and cultural backgrounds of interpreters, particularly in relation to language acquisition and education, have evolved over time. Due to the higher status and profile of signed languages and the availability of sign language acquisition courses, the pathways into SLI are diverse and, apart from deaf family connections, are triggered by general language learning interest, or direct contact with deaf people (for example, as neighbors, or in the workplace). From that starting point, many more interpreters are entering the profession through formal interpreter training programs.

Professionalization: Interpreter Training

With increased demands on interpreters working with deaf clients across a broad range of contexts, interpreter training works hard to keep pace. Different countries have a range of systems for the education, training, and accreditation of signed language interpreters. Training ranges from ad hoc intensive short courses to established formal university programs, and interpreter certification is obtained through annual testing programs or by qualification on completion of a training program (see Napier, 2009). The majority of countries start out with short courses in order to meet an immediate need via basic training. After (sometimes many) years of government lobbying, fundraising, and perseverance, a number of formal programs have been established with an infrastructure of professional regulation, monitoring and standards.

Many developing countries are still struggling to establish their SLI profession, as are some “developed” countries, such as Belgium (Haesenne, Huvelle, & Kerres, 2008). In other developed countries, however, much progress has been made. Signed language interpreters in the USA are now required to complete a Bachelor’s degree before they can become certified with the Registry of Interpreters for the Deaf. These qualifications can be in any area of study, not necessarily in interpreting. In the United Kingdom, signed language interpreters are required to have a national vocational qualification as a minimum before being admitted as a member of the Register of Sign Language Interpreters. In Australia, it is a requirement that any candidate seeking to obtain a “license to practice” at professional interpreter level from the National Accreditation Authority for Translators and Interpreters (NAATI) must have either general education to degree or diploma level in any field, or interpreter accreditation at NAATI Paraprofessional level. Higher educational requirements in these countries are attracting a different applicant pool, including people who may not have previously considered SLI as a career option.

The sites of SLI interpreter education programs reflect the move from a medical disability perspective on deafness and deaf people to a more language-based social model. SLI training has traditionally been offered in departments for disability studies, deaf studies,

welfare, or social studies; however, SLI education is increasingly becoming mainstreamed in linguistics, translation and interpreting, or language departments. In some countries SLI students are now training alongside translators and interpreters of spoken languages. While most SLI credentialing is regulated by a national signed language-specific body, a small proportion of SLI credentialing is integrated into a broader national language certification system—for example in Sweden and Australia.

In sum, it can be seen that the SLI profession has come a long way in a relatively short time and has much in common with the spoken language interpreting profession in terms of professional standards, education, and understanding of the role of the interpreter. Key differences include the involvement of deaf people in shaping the profession (from a consumer perspective as well as being practitioners themselves) and the changing demographic of interpreters entering the profession. Readers who are interested in more information concerning emerging SLI trends and future directions are referred to Napier (2011), for a more comprehensive discussion of these issues.

Signed Language Interpreting: Types, Settings, and Modes

NADJA GRBIC

Translators, interpreters, and scholars working in the field of translation and interpreting have developed particular classifications and classification systems in the course of time. First of all, we differentiate between translating and interpreting as more or less separate activities, and between translation and interpreting studies as different (sub)disciplines. We also distinguish between diverse translation and interpreting types, settings and modes, cutting up the translation–interpreting map into various different fields of practice. This entry will first offer a brief introduction to the general issues of categorization and will then focus on categorization in the field of signed language interpreting (SLI).

Categorization and Classification

Categorization is the process of classifying objects, people, practices, and even elements such as time and space as members of a category, defining them according to their similarity to other members of that category. In addition to the formal classification systems that lead deliberately to some kind of standardization, such as classification systems in libraries, ad hoc classifications fill and affect our everyday lives. Categories do not, however, exist independently of space and time; they always adjust to social and intellectual developments (see Bowker & Star, 2000; Grbic, 2010).

In the active process of classifying, we may face technical problems. One technical problem is the fact that our world is full of ambiguities (Bowker & Star, 2000, p. 24). In the translation and interpreting field, for example, there are certain events that do not fit into our traditional, normalized classification of *either* translation *or* interpreting. These are events that might include features of both translation *and* interpreting, such as signed language translation. Such instances have led to the introduction of the concept of “hybrid” forms and have called into question traditional classification systems.

SLI Types/Settings and Modes/Techniques

In the field of SLI—and interpreting as a whole—we usually differentiate between interpreting modes, interpreting types, and interpreting settings, which allows us to differentiate between various categories of practice. As Grbic and Pöllabauer (2006) have shown, those labels are not always used consistently in the literature. Here, “interpreting type” will be defined as the “context in which it occurs” and “interpreting mode” as the “way in which it is carried out” (Shuttleworth & Cowie, 1997, p. 84). “Interpreting technique” is often used as a synonym for “interpreting mode.” Spoken language interpreting literature often uses the term “type” to refer to the context in which an interpreting session occurs, whereas in the SLI literature, the term “setting” has become prevalent.

SLI Working Modes or Techniques

The invention of transmission equipment in the 1920s, which made it possible for spoken language interpreters to work simultaneously, made it necessary to differentiate between the consecutive interpreting technique which had been used until then and the henceforth technically possible simultaneous mode or technique. In the simultaneous mode, the speaker talks continuously while the interpreter renders the source text as soon as he or she has heard enough to understand, lagging a few seconds behind the speaker. To do this, spoken language interpreters sit in a booth, listen to the speaker through a headset, and deliver the text into a microphone. In the consecutive mode, the interpreter renders the target text after the source text has been delivered. Consecutive interpreting can be conceived as a continuum from rendering very small speech segments to long passages or even whole speeches (Pöchhacker, 2004, pp. 18–19).

As signed language interpreters' work spans different modalities (spoken and signed), which means that there is no acoustic overlap between source and target language, they can technically always work in the simultaneous mode. Another reason why the consecutive mode is less available to signed language interpreters is that they cannot divert their attention from the deaf client's speech (Napier, McKee, & Goswell, 2006, pp. 26–8). There are, however, linguistic and situational factors that would make consecutive interpreting a better choice. According to Russell (2005) there might be situations, especially in legal and medical settings, when the more time-consuming mode of consecutive interpreting is perhaps more appropriate as it enables the interpreters to ensure a greater degree of accuracy.

A special form of simultaneous interpreting is sight translation or sight interpreting. This means reading aloud or signing a text written in the source language for a live audience in the target language, that is, interpreting a written text in real time. In this case the interpreter's output is simultaneous not with the source text production but with the interpreter's perception of the written source text (Pöchhacker, 2004, p. 19). This can happen in many situations, such as when an interpreter is asked to interpret a patient information sheet at a doctor's office or a legal document in a courtroom setting. As sight interpreting implies a modal shift from written to spoken, it has frequently been labeled as "hybrid."

SLI Types and Settings

As interpreting takes place in various socio-institutional contexts, each of which places various different constraints on the interpreting activity, the categorization of interpreting according to interpreting type or setting is widely applied. A comparative study of standard handbooks and encyclopedias of translation/interpreting studies showed that these books describe various different interpreting types (Grbic & Pöllabauer, 2006). All of the reference works studied mention conference interpreting; court interpreting (also referred to as legal interpreting when including a greater diversity of settings, ranging from police interrogations to asylum hearings and courtroom interpreting); and community interpreting (also referred to as dialogue interpreting or public service interpreting). Two of the works also refer to liaison interpreting, practiced in commercial negotiations, and one of them mentions media interpreting. In publications on spoken language community interpreting, those types are often subdivided into subtypes or settings, such as medical settings, social settings, and so forth.

In handbooks on SLI the authors usually refer to interpreting settings when talking about the context in which an interpreting assignment occurs (e.g., Frishberg, 1990; Stewart, Schein, & Cartwright, 2004; Napier et al., 2006; Humphrey & Alcorn, 2007). Such handbooks generally describe the settings in which signed language interpreters typically work, which

are educational, legal, medical, mental health, social service, and employment settings, as well as less common, but nevertheless relevant settings such as religious, conference, and performance interpreting. Generally, these settings are explained in terms of their particular features and challenges, introducing subject-specific relevant knowledge where appropriate, as these contexts tend to vary considerably. Furthermore, these handbooks provide information in a more didactic sense, offering guidance on the standard qualifications needed for a given setting and appropriate strategies to use in order to tackle challenges, such as contextual and specialist knowledge, preparation, participants, language use, terminology, cultural issues, interpreting techniques, positioning, teamwork, role models, emotional issues, ethical issues, and so forth.

Research also reflects the importance of various different setting-specific features and socio-institutional constraints. In a bibliometric survey on research on SLI from 1970 to 2005, a corpus of 908 publications was classified with regard to the thematic focus of the texts (Grbic, 2007). Studies on a specific setting proved to be the most popular focus of interest throughout the period under study, the most prominent setting being educational interpreting (47%), followed by the legal domain (14%) and the mental health setting (10%). Interestingly, in spoken language community interpreting, the two major domains are legal and medical settings (Pöchhacker, 2004, pp. 162–3).

Typologies

In interpreting studies, several attempts have been made to establish more complex and comprehensive categorizations of interpreting events. Mason (1999, p. 148), for example, uses the variables of mode (consecutive, simultaneous, etc.), field (medical, courtroom, etc.), and tenor (addresser–addressee relationships) in order to differentiate between various interpreting types or settings. Humphrey and Alcorn (2007, pp. 159–61) put together a table of SLI events, taking the number of clients in interpreted interactions as the basic variable. For each area of work (education, religious, mental health, etc.), they distinguish between three types of interaction: one-on-one, small group, and large group. In the medical area of work, for example, we find one-on-one medical consultations with the patient, small group meetings with family or staff, and large group sessions for community health programs in larger rooms, such as a big auditorium. Other authors, such as Pöchhacker (2004, p. 24), have developed more complex and elaborate typologies. Pöchhacker's map of the territory of interpreting studies was conceived as a "spectral model" which strives to avoid clear-cut, static categories and instead allows for fuzzy edges between variable dimensions. The spectral model introduces a set of eight "vertical dimensions": medium, setting, mode, languages (cultures), discourse, participants, interpreter, and problem. Each of these comprises several "horizontal parameters." The setting dimension of the spectrum, for example, comprises a continuum of both international and intra-social settings, reaching from multilateral conferences on the left-hand side to media, court, and educational interpreting in the middle and interpreting in medical or social settings on the far right.

Translation—Interpreting Hybrids

Just as there are always ambiguities in nature, so there are events that do not fit into our traditional, normalized classification systems. Turner and Pollitt (2002, p. 41) proposed the notion of "hybrid" forms of SLI, which could open up "the possibility of revisiting our understanding of other forms and [permit] some of their richly textured hybridity to be appreciated and more fully understood." Griesel (2009), who studied (spoken language)

theater translation, sees translation–interpreting hybrids as types of interlingual transfer, which consist of phases of interpreting as well as of translating, and as such become inseparable compounds. Ashworth, even further, coined the term “transterpreting” as a hybrid form of translation and interpreting to describe interlingual, translated text chat, which is interactive written discourse in real time, possessing as such similarities to spoken discourse (O’Hagan & Ashworth, 2002, p. 14).

Signed language translation (SLT) is another relatively new category, which emerged as a consequence of digital video/DVD technology and information and communication technology on the one hand, and resulted on the other hand from certain policy measures concerning e-accessibility, particularly Web accessibility, for disabled persons. Technically speaking, it comprises the interlingual and intermodal transfer of fixed or frozen (written) texts in spoken languages into fixed or frozen signed texts (video) in any signed language. In this case, the source text is permanently available, which comprises a major difference to interpreting; the translator works without time constraint and the target text can be checked and corrected. SLT includes the translation of children’s books, religious texts, tests, handbooks for Deaf students, and so forth. SLT is often carried out by Deaf translators (see Leneham, 2005; Stone, 2007).

Other Categorizations: Specialized Techniques

In addition to the categorization of modes/techniques, types/settings, and the recently emerged domain of SLT, there are a few further categories, which are usually dealt with under labels such as “special communication techniques” (Frishberg, 1990, pp. 151–77) or “specialized interpreting skills” (Napier et al., 2006, pp. 136–59). One group involves the use of specific technology as a typological parameter, while the other is related to specific consumer groups who might not use a regional variant of a national signed language.

SLI events involving specific technologies include telephone interpreting and video remote interpreting. While during telephone interpreting the interpreter will be in the same place as the Deaf person making the telephone call for him or her, during video remote interpreting the interpreter is at a different location to one or both clients. In the USA, a differentiation is made between video relay service (VRS) and video remote interpreting (VRI). VRS involves interpreting a phone call between a hearing and a Deaf consumer through an interpreter who typically works in a relay center. VRI serves a hearing and a Deaf person who are in the same location, such as a doctor’s office, while the interpreter provides the service in a different location.

Interpreting events which are related to the communication requirements of specific user groups involve transliterating (using a variety of signing that is close to the structure of the spoken language involved); interpreting for the Deaf-blind (through either tactile signing or tactile finger-spelling); interpreting for people with minimal language skills (Deaf persons who do not have a full competency in either a spoken or a signed language); and International Sign interpreting (working in a more or less improvised, restricted, and nonstandardized contact language used at international events for Deaf people lacking interpreters into their own signed language).

SLI may also involve interpreting between different signed languages, which is frequently carried out by Deaf interpreters. They usually work in teams with a relay interpreter (Boudreault, 2005). Multilingual, multicultural assignments are multiplex, involving Deaf and hearing interpreters and ranging from interpreting for (im)migrants and minorities to interpreting in international conference settings (Locker McKee & Davis, 2010).

Silence and Participation in the Language Classroom

COLETTE A. GRANGER

In many cultures silence is an accepted and valued aspect of classroom participation and learning. However, in many (though not all) educational settings deemed “Western”—especially language classrooms—speech is highly privileged, and silence is viewed as the absence of engagement with what is being taught. Since the aim of language teaching is most often communicative competence, and production is the most readily assessed evidence of that competence, this view is understandable. Nevertheless, it may overlook important ways in which some learners use silence, including as a form of participation rather than a means of avoiding it. This discussion details how silence and participation are defined in language-learning settings and enumerates research that illustrates how sociocultural, pedagogical, relational, and intrapersonal factors influence silence and participation.

The terms *participation* and *silence* are often opposed in second language research. The former refers to activities such as raising one’s hand to speak, being active in class discussion, engaging in oral presentations, posing and answering questions, while the latter refers to the absence of such actions and, more specifically, to a lack of target language production. Learners’ silences can range from seconds-long pauses before answering questions, to the ability or willingness to speak in some situations but not all, to a “silent period” of weeks or months which, depending on the definition, can consist either of a total absence of speech (Gibbons, 1985) or of a limited stock of memorized routines and formulae that enable some face-saving as well as some communicative and social coping strategies. Because this silent period mimics the preverbal period of first language acquisition save in one aspect—it is not universal—it is of particular interest to language researchers.

Silence is of interest and concern to educators too, since production of the target language both demonstrates and reinforces learning: “When students produce the language that they are studying they are testing out the hypothesis which they have formed about the language” (Tsui, 1996, p. 146). Moreover, like all educators, language teachers are bound by curricular demands and by the requirement to assess learners’ progress. To do this they need documentable evidence, of which talk is an important component.

Many explanations for learner silence have been advanced, with sociocultural factors among the most frequently named. Some cultures and education systems—for example, Korean and Japanese (Chen, 2003), Finn (Lehtonen & Sajavaara, 1985), and Inuit (Crago, 1992) are viewed as producing reticent, passive, silent learners. Gender too has been named as a factor in silence, sometimes in conjunction with ethnicity, race, or both, as female students are often observed to participate orally much less than males (Morita, 2004; Julé, 2005). Clearly there are connections between culture, ethnicity, and gender on one hand, and classroom silence or verbosity on the other. However, to view these influences as fixed and straightforward is to ignore their interrelatedness with teaching practice as well as to gloss over individual learner differences.

Teachers have considerable power in their classrooms, and their teaching practices, which are informed by curricular requirements and institutional demands as well as by culture and by educators’ conscious or unconscious beliefs and biases, can marginalize

and even silence learners. In 1996, Tsui identified overly difficult input, inequitable speaking opportunities, and inadequate “wait time” following questions—due, she observed, to teachers’ difficulty tolerating silence—as among the ways educators contribute to reduced participation. Liu’s (2000) work with Asian students in US universities identified 110 factors influencing oral participation and its absence. While sociocultural aspects were most predictive, affective, and pedagogical factors including shyness, teacher encouragement or the lack of it, comfort, workload, and stress levels (pp. 164–5) were close behind. Similarly, Cheng (2000) named unfamiliar or unsuitable teaching methods (including those focusing on discussion and questioning or pair- and group-work) as common causes of what appeared to be learner reticence and passivity—arguing that such causes are situation-specific rather than culturally determined.

Indeed, to attribute learner silence solely to factors in the learner’s home culture can be dangerous because it overlooks the role these same cultural biases play in creating both the constructs of *silence* and *participation*, and teachers’ understandings of them. By privileging speech as a means to knowledge and understanding, a way of demonstrating learning, and a form of cultural capital (Cameron, 2000), and by making assumptions about learners that are grounded in stereotypes of race, culture, gender, and (dis)ability, teachers can produce precisely the classrooms they may be trying to avoid. For instance, Julé (2005) found conversations in a British Columbia ESL classroom heavily skewed toward male students, observing that: “the teacher appear[ed] to engage with the contributions made by the boys and seem[ed] to dismiss the contributions made by the girls” (p. 34) to the extent that the ratio of male-to-female student speech was a startling 9:1, with girls seeming little more than observers. And Ellwood and Nakane (2009) found that Australian teachers’ reluctance to call on Japanese students—whom they saw as “silent when other students engage in discussion . . . [and unable] to be critical of the material they learn, to question authority, and to speak to their teachers in a relaxed manner” (p. 217)—was rooted in stereotype and as such both negative and incorrect, as those same students reported themselves wanting to speak but lacking confidence due partly to the lack of opportunity engendered by teacher attitudes.

Confidence or the lack of it is one of many individual differences that play into learner silences, participation, or both. Others include experience, motivation, fear and anxiety, language aptitude, cognitive and learning styles, and strategies (see Saville-Troike, 1988; Tsui, 1996). For example, a study by Chen (2003) of two Korean and Japanese learners attributed their reticence to personal and family characteristics as well as cultural and educational experiences. And in regard to gender, Morita’s (2004) female Asian subjects explained their “relative silences”—partly attributable to culturally determined gender roles—in individual terms too, naming “limited content knowledge, personal tendency and preference, learning goals, identity as a less competent member, outsider or marginal status, role as a relative newcomer . . . [or] someone with limited English imposed by others, and instructor’s pedagogical style” (pp. 586–7). One study participant even gave distinct reasons for her silence in three different courses, citing as influences one teacher who she felt perceived her as “quiet but legitimate,” another who marginalized her as “relatively powerless,” and her own “strong sense of alienation” (p. 589).

Characteristics of individual teachers and students, teaching ideologies and methods and cultural aspects, and the interrelatedness of all of these can contribute to a learner’s sense of alienation in the face of a new language and, in turn, to silence. In light of this, to consider silence as only and always a lack of speech—or the absence of classroom participation—is to neglect other possibilities (Cameron, 2000; Green, 2008; Ellwood & Nakane, 2009). In 1988 Saville-Troike suggested that “a tendency in the second language learning field to equate overt production with active learning, and lack of overt production with passivity and disengagement,” had “led to an unconscious assumption that nothing

of significance was happening unless learners were talking to others" (pp. 568–9). This point is crucial, for while second language learning is clearly a social and interpersonal undertaking, it is also a profoundly *intrapersonal* process, involving the remaking of the self in and through the new language, and at times resistance to that remaking, either of which might be manifested in silence (Granger, 2004).

Often accompanying discussions of what causes silence are suggestions for ways to end it. These suggestions include: clearly communicated expectations, active teaching of questioning and interrupting strategies, and carefully designed opportunities for equitable turn taking and small-group discussion (Morita, 2004); the use of writing (Harklau, 2002) and digital technologies (Lotherington, Holland, Sotoudeh, & Zentena, 2008); soliciting and responding to learners' perceptions (Garrett & Shortall, 2002); and negotiated classroom dynamics that honor authentically reciprocal dialogue (Hayes & Matusov, 2005), and tolerate errors, alternate perspectives, and even silence (Green, 2008). This latter is crucial: to the extent that for some learners silence may have been "chosen"—deliberately or unconsciously—as a means to work through the profound intrapersonal and identity-related losses that can accompany the gains of a new language (see Granger, 2004), it may be useful for educators and researchers to work toward the recognition of, and respect for, learner silences as—in at least some cases—a positive and meaningful aspect of the language-learning process and an essential component of participation in that process.

Sinclair, John

MICHAEL STUBBS

John McHardy Sinclair (June 14, 1933–March 13, 2007) made major contributions to three related areas of applied linguistics: language in education, discourse analysis, and corpus lexicography. He was born and grew up in Edinburgh, Scotland. He studied and later lectured at the University of Edinburgh, and in 1965, at the age of 31, he was appointed to the foundation Chair of Modern English Language at the University of Birmingham, England. Although he stayed in Birmingham for the whole of his formal university career, he traveled extensively in many countries, and introduced large numbers of young researchers to work in linguistics. He was awarded honorary doctorates from the Universities of Gothenburg, Sweden, and Erlangen, Germany, and honorary professorships from the Universities of Jiao Tong in Shanghai, China, and Glasgow, Scotland. He formally retired in 2000, but continued to teach and research, and to attract leading linguists and students from around the world to the Tuscan Word Centre, an institution which, together with his second wife, Elena Tognini-Bonelli, he founded in Italy. He died at his home in Florence in March 2007.

In the 1960s, Sinclair was developing views which were, for the time, widely regarded as unrealistic, but which by the 1990s had become widely accepted. In Edinburgh and Birmingham between 1963 and 1969, he built up a computer-readable corpus of spoken language in order to study the relation between statistically defined units of lexis and psychological units of meaning. Nowadays, it is difficult to project oneself back to a period in which there were no PCs, and in which the university mainframe computer was hardly powerful enough to handle Sinclair's corpus of 135,000 running words. He argued that spoken English provides the best evidence of the common patterns of language use, that linguistic description must be concerned primarily with a theory of meaning, and he explicitly formulated several principles which are still central in corpus linguistics today. This early work tackled a question which has still not had a satisfactory answer: How can the units of meaning of a language be objectively and formally identified? Since computers in the early 1970s were not powerful enough to handle large text corpora, the work was shelved and taken up again in the mid-1980s, and the original research was not formally published until 2004 (Sinclair, Jones, & Daley, 2004).

In the 1970s, Sinclair's main focus was on educational linguistics. In one project (Sinclair & Coulthard, 1975; Sinclair & Brazil, 1982), he audio-recorded discourse in school classrooms, in order to study the prototypical units of teacher–pupil dialogue. This work emphasized the analysis of long texts, as opposed to the short invented sentences which were in vogue at the time. Again Sinclair was well ahead of mainstream thinking in linguistics. Within philosophy, work on speech act theory (by Austin, Searle and Grice) was still very new, but this Oxford “ordinary language” philosophy was not based on attested language use, but on invented data—anathema to Sinclair's approach. Halliday's work provided a general functional background, and within anthropology and sociology, work on social interaction (by Hymes, Goffman, Labov and Sacks) was becoming available, but there was little systematic linguistic description of connected discourse. Sinclair was again following the principle proposed by his teacher, J. R. Firth, in the 1930s that spoken language, especially conversation, is “the key to a better understanding of what language really is and how it

works" (Firth, 1935, p. 71), but it was only some ten years later, in the mid-1980s, that work on pragmatics became a standard topic for linguistics.

Sinclair proposed that classroom discourse is hierarchic: a classroom lesson consists of transactions which consist of exchanges which consist of moves which consist of acts. Readers immediately recognized the prototypical IRF exchange structure; a sequence of initiation—response—feedback (Sinclair & Coulthard, 1975, p. 64):

- I *Teacher*: What is the name we give to those letters? Paul?
 R *Pupil*: Vowels.
 F *Teacher*: They're vowels, aren't they?

He was also active in developing teacher-training programs. He argued that knowledge about language is "sadly watered down and trivialized" in many educational discussions (Sinclair, 1971). He directed a project which produced communicative games to meet "the language needs of urban classrooms" (Sinclair, 1973, p. 5), and another project which developed ESP materials (English for specific purposes) for the University of Malaya (Sinclair, 1980). One of his last projects, started around 2000, is *PhraseBox*, which helps children in Scottish primary schools to develop their vocabulary and grammar via real-time access to a 100-million-word corpus (Sinclair, 2006).

His work on text and discourse analysis always included literary texts. In the 1970s, along with the novelist David Lodge, his colleague in the English department at Birmingham, he developed a course on stylistics. From one end, they taught grammar through literature, and from the other end, they showed that literary interpretation required grammatical analysis. Sinclair demanded that linguistics must be able to handle all kinds of authentic texts: if it cannot handle the most prestigious texts in the culture, then there is a major gap in linguistic theory. Conversely, literary analysis must have a systematic basis: "if literary comment is to be more than exclusively personal testimony, it must be interpretable with respect to objective analysis" (Sinclair, 1971). He consistently emphasized the need to analyze long texts, and to search for observable textual evidence of meaning.

From the 1980s onwards, he returned to computer-assisted methods to study the patterning in large text corpora, and this became the basis of his most influential work as editor of a major series of language reference materials which were designed as pedagogic tools for advanced learners of English. He directed the COBUILD (Collins Birmingham University International Language Database) project in corpus-assisted lexicography, and became the founding editor in chief of a series of dictionaries and grammars. In 1987, along with a powerful team of colleagues—many of whom have made important contributions to corpus linguistics in their own right—he published the first dictionary based entirely on corpus data (Sinclair, 1987a). This was followed by a series of other dictionaries and grammars (Sinclair, 1990; Francis, Hunston, & Manning, 1996–8), plus associated teaching materials. By the year 2000, the machine-readable text collections consisted of hundreds of millions of running words, and Sinclair could show that some lexical and grammatical patterning is visible only across very large corpora.

Moon (2007), one of the senior COBUILD lexicographers, explains why the project's new data and methods had such "a catalytic effect on lexicography." When the project started there simply was no "viable lexicographic theory," whereas lexicography is now part of mainstream linguistics. However, commercial and academic priorities were not entirely compatible, and the approach was in some ways too innovative to be a total commercial success. By 1995 other major British dictionary publishers (Cambridge University Press, Oxford University Press, and Longman) had adopted the ideas, but made the dictionaries more user-friendly. It is nevertheless the COBUILD project which developed the lexicographic theory (Sinclair, 1987b).

Many of Sinclair's main ideas about corpus linguistics are formulated in what is now a modern classic (Sinclair, 1991), whose title, *Corpus Concordance Collocation*, summarizes a chronological and logical sequence. First, you need a corpus: a machine-readable text collection, ideally as large as possible. Second, you need concordance software which can identify patterns in the corpus. Third, these patterns involve collocations: the regular co-selection of words and other grammatical features. Paper concordances have been a scholarly tool since the Middle Ages, but modern concordance software can search large corpora very fast, re-order the findings, and help to identify variable phrasal units of meaning. Sinclair commissioned collocation software in the 1970s, and one of his last projects was as a consultant on a new generation of collocation software (Cheng, Greaves, Sinclair, & Warren, 2009).

Sinclair argued consistently that it is wrong to assume that the word is the primary unit of meaning: "the normal carrier of meaning is the phrase" (Sinclair, 2005). In a series of papers (Sinclair, 1996, 1998, 2005), he proposed an original phrasal model of semantic units. The overall finding of this work is that the phraseological tendency in language use is much greater than usually suspected, and that its extent can be quantified. In the last book published before his death (Sinclair & Mauranen, 2006), he continues to argue that many traditional grammars work only on simplified (often invented) sentences, but that a grammar must be able to handle raw texts of any type whatsoever. Sinclair here develops his view that significant units of language in use are multiword chunks, but the approach is via a detailed discussion of individual text fragments, as opposed to repeated patterns across large text collections. Either way, he makes a significant break with mainstream linguistic approaches.

Sinclair's work was for a long time not widely known, partly because he often published in rather obscure places, and began only post-1990 to collect his work into books with leading publishers. He was proud of the fact that, when he was appointed to his chair in Birmingham in 1965, he had no PhD and no formal publications. His first publication (Sinclair, 1965) appeared in the same year. He always remained skeptical of journals and their gate-keeping processes, which he saw as driven by fashion rather than by standards of empirical research.

In all of his work, he argued consistently against the neglect of textual analysis, which affected both linguistic and literary theory from the 1960s onwards. And his theoretical and applied interests, in discourse analysis, educational linguistics, corpus linguistics, and lexicography, were always closely related. Sinclair belongs to a long empirical tradition of British and European text analysis, derived from his own teachers and colleagues (especially J. R. Firth and M. A. K. Halliday), but represented in a broader European tradition (e.g., by Otto Jespersen) and in a much more restricted American tradition (e.g., by Charles Fries). He always saw the central task as the description of meaning. This was also true of Firth and Halliday, but it is Sinclair who made a sustained attempt to develop an empirical semantics. It led to major theoretical proposals and also to the very substantial COBUILD series of reference works. Finally, Sinclair's work is full of new observations and findings about English which were made possible by the computer techniques which he helped to invent. He is therefore one of the very few linguists who have changed the way we perceive language. In the words of one of his best known remarks: "The language looks rather different when you look at a lot of it at once" (Sinclair, 1991, p. 100).

Skehan, Peter

JANNY LEUNG

Peter Skehan (1944–) is a British linguist whose main research focus revolves around individual differences (especially language aptitude) and second language acquisition. His research interests also cover task-based instruction, language testing, and psycholinguistics. He has widely published in journals such as *Language Testing*, *Language Teaching*, *Applied Linguistics*, and *Studies in Second Language Acquisition*, and contributed chapters to many English-language teaching (ELT) and second language acquisition (SLA) books.

His popular monograph *Individual Differences in Second-Language Learning* (Skehan, 1989) laid the foundation for the budding area of individual differences (ID) research in SLA. The book reviewed learner differences such as aptitude, motivation, learner strategies, personality, and interaction between learner characteristics and types of instruction, also addressing pedagogical implications. Given the much greater variability in language development patterns amongst second language learners than those amongst first language acquirers, Skehan's work has been critical in explaining why learners differ from one another. His work marks a stark contrast with the universalist approaches, which are mostly concerned with learner similarities, and was a timely addition to the field.

In his later book *A Cognitive Approach to Language Learning* (Skehan, 1998), Skehan tackles second language acquisition from a processing perspective. With an interest in the way in which the brain processes the second language, Skehan emphasizes language learning as a cognitive activity and investigates second language learning through the cognitive abilities of the learner and the processing problems that the learner has to confront—a perspective which has largely been neglected by normative approaches to SLA. The book ambitiously touches on issues stretching from second language learning, performance, instruction and assessment, to learner styles, strategies and characteristics.

Professional Life

Skehan was born in Wales. After receiving his BA from Keele University, he pursued further studies at the University of Western Ontario and the University of the New Sorbonne (Paris III), subsequently obtaining his PhD from the University of London. The focus of his doctoral work was language aptitude.

He worked as a junior school teacher and an industrial language trainer in the United Kingdom, and taught English as a foreign language (EFL) in France. He lectured at Birmingham University and the Institute of Education, then took up a post as professor at Thames Valley University and later at King's College London before moving to the Chinese University of Hong Kong until his retirement in 2009.

Ideas

Individual Differences and Language Aptitude

Universalist accounts have dominated the study of language acquisition for several decades. Both structural and generative linguists focus their attention on the universal patterns that underlie the languages of the world. Early cognitivists such as Piaget were also mainly

interested in developmental stages and cognitive processes that are supposedly shared by all language learners. Skehan draws attention to how language learners differ, arguing that their diversity and individuality are crucial facts that any successful theory of language acquisition ought to account for. He discusses individual differences in SLA, ranging from language aptitude, motivation, learning strategies, to cognitive and affective influences, in his first monograph published in 1989. In addition to individual differences, Skehan also considers other psychological constraints in SLA such as cognitive load and attention and sees language learning from a processing perspective.

Aptitude research became marginalized as communicative approaches grew in importance; because its consequence was taken to diminish the value of individual effort, its effects were assumed to be confined to formal contexts (Krashen, 1981), and catering for different aptitude profiles did not fit the commercial interest of textbook publishers. Critic Neufeld (1979) also argues that everyone possesses language learning ability and that it is unclear what aptitude tests actually measure. Skehan (1986b, 2002) defends aptitude research against its critics by arguing that aptitude is also relevant for informal learning, and that it is of significant theoretical and practical importance for SLA. The relevance of aptitude to second language success has been reiterated by recent studies, such as Abrahamsson and Hyltenstam (2008), who have shown that native-like adult second language learners possess a high degree of language learning aptitude.

Skehan (1986a) has updated Carroll's (1965) depiction of aptitude. He proposes that it is more appropriate to see aptitude as comprising three components: auditory ability, linguistic ability, and memory ability, and that they correspond to the information processing stages of input, central processing, and output respectively. This linkage allows for the influence of individual differences on different stages of information processing. Generalizing from individual differences research and his own study on some 100 children studied as part of the Bristol Language Project, Skehan argues that some people are endowed with better cognitive and linguistic abilities for language learning than others, and that IDs in second language acquisition are connected with similar IDs in first language acquisition (Skehan, 1986b). His finding that first and foreign language aptitudes are related implies that the capacity to learn a first language, regardless of whether it is innate or established early in life, is also deeply involved in second language learning (although later, in his 2002 chapter, he acknowledges that opposing evidence was found in critical period studies, e.g., DeKeyser, 2000). Aptitude, Skehan argues, is "the second or foreign language equivalent of a first language learning capacity" (1986b, p. 200) and therefore its importance should not be undermined. To substantiate his arguments, he surveys and summarizes second language developmental stages and relates each stage to a putative aptitude component (Skehan, 2002, pp. 88–91). In considering the relevance of aptitude to existing language acquisition theories, Skehan holds that there appears to be "no place" in universal grammar (UG) which can account for individual differences (Skehan, 1986b, p. 201). Aptitude research seems to have created a puzzle for UG theorists, unless they assume that some people may be endowed with "more" of a universal grammar or possess a "more efficiently organized" universal grammar.

Skehan also criticizes the status of the Monitor in Krashen's SLA model (1985), which deals with online performance, in relation to the rest of the model, which is concerned with the process of learning over an extended period of time. He argues that the temporal separation means that individual differences that may be manifested in monitor use do not connect up with the other central components of the model, and therefore the model necessarily trivializes individual differences. In contrast, Skehan holds that the 'good language learner' model proposed by Naiman, Frohlich, Stern, and Todesco (1978) is a better explanation that demonstrates the range of potential influences on language learning success, encourages quantification of the different influences, and offers some scope

for conceptualizing interaction effects. Skehan believes that the concatenated or research-then-theory approach, as used in the Naiman model, is more suited for research into individual differences. Such an approach postulates a rudimentary categorization of relevant variables, and then implies a research program that seeks quantitative data about the variables.

Task-Based Instruction and Testing

As far as first language acquisition is concerned, Skehan has not challenged the nativist view, which holds that language development is driven by maturation factors rather than communication or input, and that prior to the end of the critical period, a language acquisition device primarily directs language acquisition processes. However, Skehan (1998) rejects the nativist approach to SLA, arguing that this model fails to generate unambiguous, testable predictions, keeps modifying itself, lacks external validity, and does not illuminate postcritical period learning processes. Taking a processing approach, he finds it more useful to see language as a dual-mode system which is learned and represented in the form of rules and exemplars. This system is constrained by the operations of a limited capacity information-processing mechanism, in which the construct of noticing is crucial. This understanding has shaped Skehan's view on pedagogy. He regards the 3P approach (presentation, practice, and production) as "out of fashion" (Skehan, 1996) and advocates the task-based approach to instruction and testing, which is believed to engage the learners' naturalistic acquisition system, stretch the underlying interlanguage system and drive development forward. Processing-based analysis of tasks assesses their information-processing load, which is useful for the task designer who needs to strike a balance between the attentional demand of language use and development, as well as that between a concern for form and for meaning.

In his characterization of tasks, Skehan emphasizes that meaning should be primary, and that tasks must bear a relationship to comparable real-world activities. Skehan (1992) proposes a three-way distinction of the analysis of tasks, based on code complexity, cognitive complexity, and communicative pressure. These task dimensions shed light on task difficulty, which in turn determines how much processing resources the learners are left with for a focus on form. It is believed that attention is needed for noticing and interlanguage change, and greater attention to form can lead to higher levels of accuracy. Encouraging an adequate focus on form is deemed particularly important for older learners, whose natural predisposition is toward meaning, and this predisposition is potentially harmful to their second language development. Much of the difficulty faced by the second language learner is in having to cope with performance, which is biased toward meaning, while controlling the complex second language system. This tension between form and meaning exists at any moment of language use.

Extending from his interest in the use of tasks in instruction, Skehan (2001) uncovers the systematic effects that task characteristics (including familiarity of information, dialogic versus monologic; degree of structure; complex outcomes; and transformation) have on assessment performance. Task-selection decisions are found to have significant consequences on the fair treatment of candidates, and therefore tasks should be taken as a relevant unit for the design of tests. More specifically, a variety of processing conditions should be built into assessment in order to allow the test results to be generalized to a range of performance conditions. Indeed, Skehan argues that the method of assessment is not a technical problem, but the central problem in assessment, since it forms the basis of how language is elicited, how performance is engaged and what implications can be drawn about the candidates' language ability. The task-based performance literature may be further linked with the Levell model of first language speaking to distinguish between factors that address the complexity of tasks and factors that affect the way in which expressions are built (Skehan, 2009a).

All in all, Skehan believes that psycholinguistic studies deserve greater attention by language researchers, and he has made it a constant theme in his work that a better understanding of psychological processes is fundamental to advancing and unifying the study of language learning, teaching, and assessment. He calls for further research into the role of memory and attention in second language processing, and this focus is reflected in his recent work involving empirical studies on lexical performance, the effects of strategic planning on performance, etc. (Skehan, 2009b; Skehan & Foster, 2005).

Skutnabb-Kangas, Tove

ROBERT PHILLIPSON

Tove Skutnabb-Kangas (TSK), born July 6, 1940, grew up in Finland with two mother tongues, Finnish and Swedish. She studied Nordic philology, education, and psychology at the University of Helsinki and had the good fortune, directly after her MA, to be employed as a research assistant to Einar Haugen at Harvard University, USA in 1967–8. Haugen played a key formative role in establishing fields that have flourished over the past half-century: bilingualism studies, language policy, and the ecology of language. When TSK returned to Finland she was instrumental in these topics being introduced in academic and policy contexts in the Nordic countries. This led to a career with a major worldwide impact on multilingual education, minority studies, linguistic human rights, language policy and power, and the relationship between biological, cultural, and linguistic diversity. Her impact has been twofold: on academic scholarship and on involvement in ongoing struggles for justice.

TSK taught in a variety of contexts while preparing a PhD thesis (Helsinki, 1975) on the school achievement of Swedish mother-tongue boys in a bilingual vocational school in Finland. In the theoretical part, she systematized definitions of mother tongues (languages learned first, identified with, best known, or most used)—these are now often used as default definitions. Later she also ranked the definitions in terms of how much they respect linguistic human rights, stating that the identification definition is the only reliable one, and that one can also have a mother tongue which one does not know (particularly well)—central for revitalizing the mother tongues of indigenous peoples that have been unlearned through forced assimilation. She later wrote an advanced doctoral thesis (DPh, Roskilde, Denmark, 1987) on language and power, and the education and identity of migrant minority, working class Finnish children in Sweden. The empirical evidence unambiguously demonstrated that mother-tongue-based bilingual education could deliver in ways that submersion into a monolingual alien language and culture never could. She has also systematized definitions of bilingualism (Skutnabb-Kangas, 1975), and characteristics of bilingual education models and prerequisites for successful education (e.g., Skutnabb-Kangas, 1981, 1988, 1995, 2000).

TSK and Pertti Toukomaa, a Finnish social psychologist, wrote two monographs for UNESCO, *Teaching Migrant Children's Mother Tongue and Learning the Language of the Host Country in the Context of the Socio-Cultural Situation of the Migrant Family* (Skutnabb-Kangas & Toukomaa, 1976) and *The Intensive Teaching of the Mother Tongue to Migrant Children of Pre-School Age* (Toukomaa & Skutnabb-Kangas, 1977). These publications ensured that their ideas were disseminated worldwide and made for links with key scholars in bilingualism, in particular from Canada, India, and the United States. She has been deeply involved in minority education issues in Sweden and Norway since the late 1960s, in relation to both immigrant minority and indigenous education, including successful struggles for the only indigenous peoples in European Union countries and Norway, the Saami. Mother-tongue-medium education from preschool to university level is now a reality for some Saami.

After a UNESCO conference in Paris in 1972 where Wallace Lambert presented the first results of Canadian immersion education of English-speaking students through the medium of French, TSK suggested similar experiments in Finland for Finnish-speaking dominant

group children through the medium of Swedish (*Multilingualism for All*, see Skutnabb-Kangas, 1995). All was clear—parents, children, the municipality—but a change of Minister of Education postponed immersion in Finland for another ten years.

TSK moved to Denmark in 1979, which has given her firsthand experience of life as an immigrant. This has been challenging: Denmark markets itself as progressive and liberal, but has subjected its entire immigrant and refugee population to crudely assimilationist policies, culturally and linguistically. Her empathy with the struggles of indigenous peoples and marginalized minorities worldwide has had a deep influence not only on these peoples themselves but also on the focus of her work. This led to seeing discrimination on grounds of language having ideological and structural functions similar to racism and sexism. The concept *linguicism* was coined by TSK in 1986 and put to practical academic use in a range of contexts. She defined it as “Ideologies, structures and practices which are used to legitimate, effectuate, regulate and reproduce an unequal division of power and resources (both material and immaterial) between groups which are defined on the basis of language” (Skutnabb-Kangas, 1988, p. 13).

Her book *Tvåspråkighet* (in Swedish 1981, in English 1984, *Bilingualism or Not—the Education of Minorities*) showed powerfully that matters of language, education, and culture needed to be situated in their economic and political contexts. A multidisciplinary approach has been a cornerstone of her research since that time. Phillipson edited a volume in 2000 to celebrate TSK’s 60th birthday, *Rights to Language: Equity, Power and Education*. The volume has 50 contributors from anthropology, applied linguistics, communication, discourse analysis, economics, education, law, linguistics, media studies, policy analysis, political science, psychology, social theory, and sociolinguistics, as well as creative writers. All the contributors were people who had influenced TSK’s professional development and who were influenced by her work.

Since the early 1980s TSK has worked closely on postcolonial education issues and the role of English worldwide. This interest was initially triggered by involvement in NGO educational “aid” from Norway and Denmark to the Namibian liberation movement, SWAPO, which was then in exile. Linguistic imperialism, a type of linguicism, has had a major influence on the policies of donor countries and the World Bank, consolidating the position of former colonial languages and English as the dominant language of corporate globalization and United States interests. These influences on language policy are covered in her 2000 magnum opus (818 pages), *Linguistic Genocide in Education—or Worldwide Diversity and Human Rights?*

A further central concern for almost 40 years has been developing the concept of linguistic human rights. This has required looking in depth at the evolution of relevant national and international laws, and making a case for language rights as fundamental human rights. This is now increasingly accepted, though the struggle for the implementation of such rights is uphill in most parts of the world, as can be seen from the many contributions to two coedited anthologies, *Linguistic Human Rights: Overcoming Linguistic Discrimination* (Skutnabb-Kangas & Phillipson, 1994), and *Language, a Right and a Resource: Approaching Linguistic Human Rights* (Kontra, Phillipson, Skutnabb-Kangas, & Váradi, 1999).

TSK has written over four hundred scholarly articles, on such topics as the linguistic oppression and lack of linguistic human rights of Kurds in Turkey, of the Deaf and their sign languages, and of many indigenous peoples worldwide. Her books and articles have appeared in almost 50 languages. TSK has lectured worldwide, studied language policy issues on most continents, and been a keynote lecturer at hundreds of international conferences. She has functioned as an expert for many international bodies, including UNESCO, the Council of Europe, the High Commissioner on the Rights of Ethnic Minorities of the Organization for Security and Cooperation in Europe, and the UN’s Permanent Forum on

Indigenous Issues. She has been involved in the establishment of minority multilingual education schemes in many countries, including Nepal and India. These innovations are an encouraging sign that some governments in postcolonial countries are introducing mother-tongue-based multilingual education, as documented recently in two anthologies (Skutnabb-Kangas, Phillipson, Mohanty, & Panda, 2009; Skutnabb-Kangas & Heugh, 2011).

TSK was the vice-president of Terralingua for its first seven years. Terralingua works “to sustain the biocultural diversity of life—the world’s invaluable heritage of biological, cultural, and linguistic diversity—through an innovative program of research, education, policy-relevant work, and on-the-ground action” (from the mission statement, at www.terralingua.org), and worked especially to connect the more biodiversity-centered issues in the organization to educational linguistic human rights as central for promoting endangered languages and knowledges (Maffi, Skutnabb-Kangas, & Andrianarivo, 1999; Skutnabb-Kangas, 2001; Skutnabb-Kangas, Maffi, & Harmon, 2003; see also Skutnabb-Kangas & Phillipson, 2008; Skutnabb-Kangas, 2011).

Two expert papers for the United Nations Permanent Forum on Indigenous Issues, written with Robert Dunbar, an international human rights lawyer, and indigenous colleagues (Magga, Nicolaisen, Trask, Dunbar, & Skutnabb-Kangas, 2005; Dunbar & Skutnabb-Kangas, 2008), led to the publication of the path-breaking monograph *Indigenous Children’s Education as Linguistic Genocide and a Crime Against Humanity? A Global View* (Skutnabb-Kangas & Dunbar, 2010). These publications show that to educate indigenous/tribal and minority children through a dominant language in a submersion or even early exit transitional program violates the right to education. It prevents access to education because of the linguistic, pedagogical, and psychological barriers it creates; it often curtails the development of the children’s capabilities and thus perpetuates poverty; and it is organized against solid research evidence about how best to reach high levels of bilingualism or multilingualism and how to enable these children to achieve academically in school. They also consider the extent to which the various forms of submersion education practiced both earlier and today by states could be considered to give rise to *international criminal responsibility*, exploring the application of the legal concepts of genocide and of crimes against humanity.

TSK is on the editorial boards of many international scientific journals. She is the editor of the book series *Linguistic Diversity and Language Rights* (see also activities and publications on her quadrilingual Web site, www.tove-skutnabb-kangas.org). TSK was the recipient of UNESCO’s Linguapax prize in 2003.

Snow, Catherine

M. SUSAN BURNS AND ARIEH SHERRIS

"It's time for dessert, Nina. What's hibernating in the freezer?"

"Ice cream?"

"Yes!"

This is an exchange between Catherine Snow and Nina, almost three years old, the first author's daughter, at a joint family gathering at Snow's home. Nina's mother thought, here we go, a new vocabulary word "hibernating" for Nina! Snow, of course, was contextualizing her chosen low-frequency vocabulary item in a simple stock question form and a familiar context (i.e., dinner, dessert, and freezer). The example reflects Snow's personal dedication to the role of input, spontaneous modifications, interaction, and linguistic environment, a dedication that has lasted 40 years and revealed itself in studies of family table talk, pragmatics, syntax, vocabulary, and literacy in first and second language learning, producing research that has influenced nearly two generations of researchers, teachers, and language and literacy policy makers worldwide. In an early peer-reviewed publication based on her dissertation Snow wrote "mothers under properly motivating conditions can predict to some extent what kinds of speech modifications their children will require . . . the presence of the child remains a potent factor in eliciting still more extensive modifications" (Snow, 1972, p. 557).

Catherine Elizabeth Snow, born December 14, 1945, in Toledo, Ohio, received her BA in psychology in 1966 from Oberlin College in Oberlin, Ohio, and was awarded highest honors, Phi Beta Kappa, for her thesis titled "Effects of Luminance and Contrast on Contour Dependent Color After-Effects." In 1967, her thesis "Conjunctive and Disjunctive Thinking in Children" led to an MA in psychology from McGill University in Montreal, Quebec. In 1971 McGill University awarded Snow a PhD in psychology for her thesis "Language Acquisition and Mothers' Speech to Children."

Snow described her career as well as her work in second language development as being impacted by her appointment at the Institute for General Linguistics, University of Amsterdam in Amsterdam, the Netherlands from 1971 to 1978 (personal communication, 2010). Under examination at that time was sequential second language acquisition of Dutch by 5- to 7-year-old immigrant children. Concurrent research activities included a variety of linguistics projects in which Snow became lead statistician at the Institute. Snow describes her research at that time and in future scholarship as

enabling me recurrently to see links from current topics to new ones . . . I started out studying language development in young children . . . and then because I was in Holland got interested in first language acquisition and second language acquisition in the ways that they were similar and different . . . then moving to Harvard and thinking about literacy development . . . children again using the resources of social interaction to construct models for this new domain. (personal communication, 2010)

Selected areas in which Snow has made significant impact on approaches to second language development are highlighted below, keeping in mind that this work is intimately

related to her initial interest on first language acquisition. In a similar manner additional work in early language and literacy are also highlighted.

An early advocate of psychosocial concepts of L2 and bilingual acquisition, Snow has conceptualized in her laboratory and naturalistic research (Snow & Hoefnagel-Höhle, 1978) that older learners acquire a new language more rapidly than younger ones as part of her critique of maturational constraints on L2 acquisition. In her critique of critical/sensitive period hypotheses for second and bilingual language acquisition, Snow and her colleagues demonstrate numerous neurological and cognitive studies of SLA are flawed (Marinova-Todd, Marshall, & Snow, 2000); this stand has generated considerable controversy (Hyltenstam & Abrahamsson, 2001), which she and her colleagues address (Marinova-Todd, Marshall, & Snow, 2001).

In the mid-1980s, Snow, together with Brian MacWhinney, developed the child language data exchange system (CHILDES) (MacWhinney & Snow, 1985). CHILDES was conceived as a collection of corpora openly accessible to researchers to both contribute corpora and research the corpora of others. The database has produced a wealth of research from several different disciplines. Today it can be accessed via the Internet (<http://childes.psy.cmu.edu/>). Much of Snow's data used for the purposes of studying first and second language acquisition and establishing durable linkages between oracy and literacy has been subsequently contributed to CHILDES (e.g., Snow & Dickinson, 1990; Snow, Perlmann, & Nathan, 1994).

The theme of building language for literacy is echoed throughout Snow's work on literacy development and recommended practices: a longitudinal study of language and literacy development among low-income children who were followed for 15 years from age three (home-school study); following the language development of young children participating in the early head start intervention; studying the language and literacy development of first and second language learners; and considering aspects of transfer from L1 to L2 in the domains of language and literacy. Results of these studies have shed light on the development of language and literacy as well as key components that are integral to early intervention in these areas. Decontextualized language and use of rare words by families at home and teachers at school (including preschool) are associated with students' literacy acquisition in kindergarten as well as reading comprehension through high school (Snow & Tabors, 1993; Snow, Tabors, & Dickinson, 2001; Snow, Porche, Tabors, & Harris, 2007). Results related to language and literacy development and vocabulary transfer from L1 for L2 learners includes a study of cognate instruction with Spanish-speaking learners of English that showed positive impact of such instruction on reading comprehension (Carlo et al., 2004).

Her jointly authored book, *Preparing Our Teachers: Opportunities for Better Reading Instruction* (Strickland, Snow, Griffin, Burns, & McNamara 2002), is one of several efforts she has been involved in to develop consensus among teacher-educators about what pre- and in-service elementary teachers need to know about language and literacy, in particular to serve second language learners effectively. Snow has also written about bilingualism and its relation to language policy issues such as bilingual education in the United States and in developing nations, and about testing policy. She is currently involved in efforts to improve middle-school literacy outcomes, in partnership with other Boston area researchers and the Boston public schools.

Catherine Snow's policy work includes chairing a number of national panels, including the National Academy of Sciences committee that prepared the reports *Preventing Reading Difficulties in Young Children* (1998) and *Early Childhood Assessment: Why, What, and How* (Snow, Van Hemel, & Committee on Developmental Outcomes and Assessments for Young Children, 2008), the RAND Reading Study Group that prepared *Reading for Understanding: Toward an R&D Program in Reading Comprehension* (2002) and the National Academy of

Education's Study group that prepared the report *Knowledge to Support the Teaching of Reading: Preparing Teachers for a Changing World* (Snow, Griffin, Burns, & NAE Subcommittee on Teaching Reading, 2005). Findings related to second language learners are encountered throughout these reports; consider, for example, in *Preventing Reading Difficulties in Young Children* (Snow, Burns, & Griffin, 1998, p. 11),

If language-minority children arrive at school with no proficiency in English but speaking a language for which there are instructional guides, learning materials, and locally available proficient teachers, these children should be taught how to read in their native language while acquiring proficiency in spoken English and then subsequently taught to extend their skills to reading in English.

If language minority children arrive at school with no proficiency in English but speak a language for which the above conditions cannot be met and for which there are insufficient numbers of children to justify the development of . . . such conditions, the instructional priority should be to develop the children's proficiency in spoken English.

In a similar manner her work on many other policy panels and projects, for example, *English Plus: Issues in Bilingual Education* (Cazden & Snow, 1990), *Achieving High Educational Standards for All* (Ready, Edley, & Snow, 2001) and the *Strategic Education Research Partnership* (Donovan, Wigdor, & Snow, 2003, and ongoing) have impacted bilingualism and language policy issues in the United States and developing nations.

In conclusion, Catherine Snow's research, policy, and practice span three main areas: (a) language acquisition, language socialization, and parent-child / child-child interaction; (b) bilingualism, second language acquisition, and bilingual education; and (c) literacy and language-literacy relations. Her major contributions include: (a) language acquisition as the root of literacy in both first and second language but also literacy acquisition as the necessary continuation of language acquisition, reflecting her belief that full-fledged adult academic language skills are not accomplished without literacy; (b) the importance of addressing all areas of language, including pragmatics and vocabulary, when examining social interactive facilitation of language learning and when thinking about language assessment or the relation of language and literacy; and (c) the importance of knowledge about both first and second language acquisition for teachers of literacy.

Social Evaluation of Second Language Speech

JENNIFER MILLER

Introduction

In a time of unprecedented mass global movements of people, the number of people who use more than one language to communicate has never been greater. International migration is at record levels, as are numbers of refugees and asylum seekers. Trends dictating global flows of people are driven by armed conflict, growing economic integration and globalization, increasing transnationalism and technological innovation, population growth, climate change, and human-made disasters. One consequence is the flow of languages across the world, to the point where plurilingual, multicultural societies are the norm in many countries, and in many world cities hearing other languages and many varieties of the dominant language is a daily occurrence. As people begin to learn and use the dominant language in their new countries, it is important to address how their language use is viewed and heard by others.

The idea that people make judgments about the speech of others is far from new. In 1913, Shaw's renowned play *Pygmalion* showed that social acceptance and legitimacy at different echelons of society can be manipulated via speech. Giles and Powesland's (1975) *Speech Style and Social Evaluation* set the agenda for many researchers to explore social judgments about speech, as well as language attitudes, and the ways we accommodate (or don't) to the speech of others. In recent times, research has tied social judgments about spoken language to identity, power, and legitimacy, in both first (L1) and second language (L2) use. In the case of the latter, the traditional binary of native speaker vs. non-native speaker, and assumptions about native speaker competence, have been challenged (Lippi-Green, 1997; McKay, 2003; Miller, 2009). In both cases, the role of the hearer has become a central focus. This entry is about the judgments people make about the social language use of L2 speakers, about the speech and the speaker.

Before turning to such judgments, it is important to clarify the notions of context and competence in L2 use. People have multifarious purposes for learning or using an L2 and achieve these purposes to varying degrees of success. This entry focuses on the second or additional language use of speakers who have developed some (but not near-native) fluency in the language, and are heard by mainstream native or near-native speakers of that language. That is, the social evaluation concerned is of a recognizably non-native user by a native or dominant language speaker. It is also understood that the "second" language may in fact be a third, fourth, or any additional language for a speaker.

Evaluating the Non-Native Speaker

The internationalization of English has caused many to rethink the notions of native and non-native speaker. To give some idea of context, Graddol (2006) estimates that numbers of people learning English will peak at two billion by 2020, and currently a billion people

use English as an L1 or lingua franca. In addition, the vast majority of English-language teachers around the world are now “non-native” users of English (Matsuda & Matsuda, 2001).

The complex practical activity of speaking constructs aspects of identity, but also requires the collaboration of the listener, who must not only hear but, as Bourdieu (1991) points out, must also believe. What are the implications for those who are heard to speak with an accent, or to use nonstandard forms of any language? All too often, their speech is used to subordinate them socially. Lippi-Green (1997) insists that standard language and non-accent are abstractions. She suggests there are ideological aspects of standard language, which represent “a bias toward an abstracted, idealized, homogenous spoken language which is imposed by dominant bloc institutions and which names as its model the written language of the upper middle class” (p. 64). Lippi-Green outlines what she terms a “language subordination model,” a system through which speakers who are heard as different may be systematically marginalized at school, in the workplace, and in the media. She provides evidence that accent, for example, may become a “litmus test for exclusion” (p. 64).

Munro and Derwing (1999) focus on the intelligibility of L2 speech, noting that accent is only one factor of many that determine what kind of a hearing an L2 speaker receives. In fact, they observe that L2 speakers who are judged to have very strong accents can be nonetheless intelligible and highly comprehensible to most or all listeners. A later study (Derwing, Rossiter, & Munro, 2002) looked at difficulties faced by native speakers in understanding Vietnamese-accented English. It was found that training in phonological and cross-cultural awareness improved the native speakers’ comprehension and the quality of their interactions with non-native speakers.

In Llurda’s (1993) study on language proficiency and social acceptance, native speakers recorded their perceptions of utterances by unseen non-native speakers. Llurda found that high levels of proficiency were perceived by listeners as indicators of strong educational background and intelligence, but also of attractiveness, self-confidence, and leadership qualities. A number of studies, starting with Giles and Powesland (1975) and Bourhis, Giles, and Lambert (1975), also indicate that listeners make critical social judgments about speakers, even without seeing them. These can include judgments about intelligence, status, education, and class (Giles & Coupland, 1991). And so the sound of someone’s speech can be a marker of inclusion, exclusion, and difference. Additionally, in spoken interactions, Giles and Coupland’s concepts of *convergence* (building solidarity with the speaker) and *divergence* (establishing distance) reflect both evaluation and the way the listener chooses to position himself or herself in relation to the speaker.

The social evaluation of an L2 (including proficiency) may be used by native speakers as a basis for discrimination. In a world characterized by increasing diversity, as well as dislocation and social and cultural inequalities, McKay (2003) suggests that “it is time to recognize the multilingual context of English use and to put aside a native speaker model of research and pedagogy” (p. 19). Yet frequently institutions and teachers are complicit in promoting a standard language ideology which rejects or marginalizes certain varieties of English. In language testing, for example, scales measuring L2 proficiency reserve the highest levels for the near-native or native-like speaker or writer. Maum (2002) shows that in the teaching English to speakers of other languages (TESOL) workplace, non-native speakers often face discrimination based on accent and “credibility.” Other studies also indicate that non-native English speakers struggle to achieve legitimacy within the field of TESOL, and are not assigned the status and power of native speaker teachers (Duff & Uchida, 1997). This is a tangible example of how sounding different can have social and material consequences, as well as shape the social and professional experience of speakers. In this way, a negative view of someone’s speech is also an attack on their identity. As Lippi-Green (1997) writes, “the evaluation of language effectiveness—while sometimes

quite relevant—is often a covert way of judging not the delivery of the message, but the social identity of the messenger” (p. 17).

Identity and Second Language Use

The role of language in constructing identity has frequently been demonstrated by research. Identity has been described as “relational, constructed and altered by how I see others and how they see me in our shared experiences and negotiated interactions” (Johnson, 2003, p. 788); “an account of oneself and others in a relationship of reciprocity and mutual recognition” (Létourneau, 1997, p. 61); and “Being recognized as a certain ‘kind of person’ . . . connected not to internal states but to performances in society” (Gee, 2000–1, p. 99). The common threads here are that identity is relational, negotiated, discursively constructed, and socially enacted, and that being recognized and heard by others is a critical part of the representation of identity. A recent case study of a young Hispanic woman (Varghese, Morgan, Johnston, & Johnson, 2005) highlighted the conflicting and evolving identities of non-native teachers who become English teachers. Marc (the teacher in question) lists some of the labels or ways her identity has been ascribed since she left Mexico, as follows: “Here I was/am an ESL learner, Latina, Mexican, woman, single, Catholic, student of colour, NNEST [non-native English-speaking teacher], minority, Hispanic, bilingual, and I don’t know what else . . . people just label me” (p. 27). Note that most of these labels refer directly or indirectly to her language use, with the possible exception of “woman, single, Catholic.” The authors stress, however, that notions from social and psychological identity theory such as in-group and out-group identities are too oppositional and static, and do not account for the shifts and indeed progress made by speakers in different social interactions. Marc’s labels above hint at the breadth of the elements which comprise her identity and the ways in which she is perceived.

If one accepts the idea that identity is relational, interactional, and contextualized socially, it cannot be viewed as an “*entity*,” but rather needs to be seen in relation to discursive, social, cultural, and institutional practices, tied to processes of legitimization and power. It also means that one should not underestimate the power of the hearer to accept or reject the spoken discourse of L2 speakers.

Ways of Hearing Second Language Speakers

In his introduction to Bourdieu’s *Language and Power* (1991), Thompson writes that in Bourdieu’s terms, “differences in terms of accent, grammar and vocabulary—the very differences overlooked by formal linguistics—are indices of the social positions of speakers and reflections of the quantities of linguistic capital (and other capital) which they possess” (p. 18). In the multilingual contexts described above, L2 speakers are faced with communicating in the dominant language of a particular country. For example, the 150 language groups of Australia need to learn and to speak English to participate in education, the workplace, daily functional interactions, and social settings. As Bourdieu indicates, accent, nonstandard grammar, or any struggle to express meanings may become part of the evaluation of the hearer, who may accept or deny both the message and the identity of the speaker. A speaker’s experiences in “finding a voice” may vary widely depending on their personal resources, such as language proficiency, social capital, personal biography, interactional skills, knowledge, and attitudes (Miller, 2009). Negative evaluations of L2 speech may be consequential for the speaker in social, professional, and psychological terms. Accent, as Lippi-Green (1997) observes, sometimes functions as “the last back door to discrimination” (p. 73). In summary, one cannot view L2 speech in isolation from social and cultural practices, or speaking in isolation from hearing (Miller, 2003).

Research by Carrier (1999) uses the related notion of social status with regard to L2 listening and comprehension. She concludes that social relationships have an effect both on language behavior and on conversational interaction, and therefore also impact on listening comprehension. That is, it seems likely that knowing someone beyond a superficial acquaintance may change the way we hear, and lead to more productive interactions. Carrier also demonstrates that a strong accent does not equate with poor intelligibility.

Reframing the Social Evaluation of Second Language Speech

The listener has significant power to allow speakers to become audible to dominant language speakers. In a study of the role of language in self-representation for immigrant students in Australia, Miller (2003) suggests that for those still acquiring a language (as many L2 speakers are), the way people are heard by English speakers is just as important as how they speak English. As one year 11 Taiwanese student said,

If your English is as fluent as Australian students, the Australian students do not really see you that much differently. I saw them talking to those Asian students whose English is good in the same way as they would to other Australian students. (p. 170)

Miller's model and theorization of audible difference, language use, and identity outlines the interrelationships of language competence, social capital or status, audibility, legitimacy, and the social conditions needed for the negotiation of identity (p. 176). The role of the hearer as arbiter in the model makes it possible to generalize some principles in the social evaluation of L2 speech.

Unlike a quantitative academic judgment about language proficiency, the social evaluation of L2 speech occurs in many professional and social contexts and through multiple social interactions on a daily basis. The collaboration of the listener is a part of these interactions, and on the basis of the kinds of social evaluation made, the listener may choose to support the L2 speaker in the interaction, or to abandon them. Speakers may demonstrate many aspects of language proficiency, but be perceived as L2 speakers due to their accents, intonation, grammar, vocabulary, or other prosodic features. Hearers also take into account aspects of the speaker's identity, including social status. For example, a Chinese businessman whose sometimes unintelligible English has been described as "mangled" and "Chinglish" may find it hard to get a hearing. But if that man is also John So, the longest-serving lord mayor of Melbourne (2001–8), many things change. John So was wealthy, innovative, energetic, and an effective mayor, and he enjoyed a cult status in the city, especially among young people, partly because of his "funny English" and good humor about it. In other words, his social and political status was a key to how he was heard as a speaker.

For speakers who do not enjoy a privileged social status, the response of listeners may be tied to social attitudes and a willingness to accommodate L2 speakers. The problem for some L2 speakers is that they find it hard to establish social relationships when their use of the dominant language is still insecure. Norton and Toohey (2001) remind us that access to social communicative events is critical for L2 speakers to progress, to integrate socially, to represent their own best interests, and to negotiate their identities. The dominant language community may or may not open up possibilities for learners to practice and to participate in these critical social interactions.

It seems important that native speakers of any language learn how to listen to those who are using a second or additional language, or one they may still be acquiring, and how to hear above the noise of difference. This has been referred to as "taking the mainstream headphones off" (Miller, 2003, p. 177), to make space for new and emerging voices

to be heard. The danger of negative evaluations of those who sound “different” is the very real danger of social exclusion and discrimination.

Social Influences on Second Language Speech Acquisition

JETTE G. HANSEN EDWARDS

Social influences on second language (L2) speech acquisition are external or environmental factors that impact L2 learning and use. While numerous influences could be defined as social, the most commonly researched are length of residence (LOR) in the L2 environment, amount/extent of first language (L1) and L2 use, gender, social identity, target language variety, and interlocutor accommodation. Research on social factors began in the 1970s, influenced by work in sociolinguistics by Labov and colleagues on L1 variation. While a number of the influences investigated by L2 researchers, namely LOR and gender, have attracted a great deal of interest, the majority of the factors have been under-researched and underrepresented in the literature. However, social factors may have a significant effect on the acquisition and use of the L2 as findings from research on social factors convincingly shows that learners are

active agents in their language use, language choices, and targets for acquisition. That is, they are not passive recipients of the target language, and variation in production is typically systematic, and may be due, in part, to social marking due to gender, identity, accommodation, to the interactant, and the linguistic environment, etc. (Hansen Edwards, 2008, p. 251)

LOR has received the most attention in research on social influences, under the premise that a longer LOR equals greater quality and quantity of L2 input and use. It has typically been researched as a predictor variable of L2 accent and measured through native-speaker accentness ratings of sentences spoken by L2 learners. However, despite the greater attention paid to LOR, firm conclusions cannot be drawn due to mixed results of the research; additionally, LOR is often confounded with age of arrival (AOA) as the learners with the longer LORs have often also arrived in the L2 culture at an earlier age. The real effect of AOA and LOR may be due to differences in the learning environment as younger arrivals typically have richer L2 use environments due to peers and schooling. This may be the case for differences between younger and older children as well: In their work with Chinese L2 learners of English, Jia and Aaronson (2003) found that children with a younger AOA tended to develop more L2 networks and retain fewer L1 friends while children with an older AOA preferred to retain L1 social networks. After several years in the L2 environment, the younger children had a higher proficiency in the L2 than the older children. An additional concern is that a longer LOR does not in itself guarantee greater L2 use as LOR does not measure quality and quantity of L2 input and interaction; learners can have a long LOR in the L2 culture and still have primarily L1 social networks and L1 use opportunities. To address this concern, a number of studies (e.g., Guion, Flege, & Loftin, 2000) have focused on the amount/extent of L1, L2, or both L1 and L2 use instead of LOR. While early research on the amount of L2 use found that it did not appear to affect L2 accent, more recent research suggests that greater L2 use and contact with native speakers results in increased L2 fluency and decreased L1 accent. Confirming research on LOR, the research

on extent of L1/L2 use also suggests that an early AOA increases the chance that learners form L2 social networks and have greater L2 use opportunities. As Flege, Frieda, and Nozawa (1997) state, the level of attachment learners have to the L1 community and openness to sound like native speakers of the L2 may be related to their AOA in the L2 culture. Finally, research indicates that it may not only be greater L2 use that affects L2 accent, but also decreased use of the L1 that has an effect, a finding that has been corroborated by research by Flege and colleagues (Flege et al. 1997; Guion et al. 2000). L2 speakers with a higher use of the L1 have stronger L1 accents than those who do not speak the L1 frequently. Age effects on L1 use are unclear: While some research found that L1 use affected L2 accent regardless of AOA, other studies have found that AOA did impact L2 accent, in some cases more than L1 use.

Research (Rehner, Mougeon, & Nadasdi, 2003) on the acquisition of linguistic variation by L2 learners has also focused on whether immersion/study abroad experiences or contact with native speakers of the L2, or both enable learners to acquire native-speaker L2 sociolinguistic variation patterns. Findings suggest that learners who have immersion experiences in the L2 culture or home-stay experiences with members of the L2 culture acquire similar variation patterns to native speakers of the L2 and that an increased amount of contact with native speakers results in greater usage of native-like variation patterns.

Gender is also a commonly researched social factor. Early research on gender operationalized it as "sex," and employed it as one of a number of predictor variables for pronunciation accuracy; however, as Piske, MacKay, and Flege (2001) note in a review of these studies, the findings are mixed and no conclusions can be drawn on the effect of sex on pronunciation accuracy. Current research views gender as a social construct and examines how gender affects use of different L2 variants, resistance to use of particular L2 features, and access to L2 use opportunities. Similarly to the findings from L1 sociolinguistic research (Coates, 1993) which has found that in many speech communities, women use more prestige variants than men, L2 research (Adamson & Regan, 1991) has also found that women typically use more formal variants than men, suggesting that different L2 norms are being targeted based on gender, with the L2 women targeting the speech norms of native-speaking women and the L2 men targeting the speech patterns of native-speaking men. For example, Adamson and Regan (1991) in research on Vietnamese and Cambodian L2 speakers of English, found that the women had a higher use of the prestige form of {-ing}, which is [ɪŋ], than the men, who conversely had a higher use of the less prestigious variant [ɪn], leading Adamson and Regan to hypothesize that the learners were targeting the gendered {-ing} use patterns of the native speakers in their community. Gender may also affect language choice, as findings from research suggests. Ohara (2001) and Siegal (1996) both examined the L2 use of Western women learning Japanese; it was found that some women resisted using particular features of the L2 that they perceived would create a gendered identity in the L2 that was in conflict with their L1 identity. For example, the women in Siegal's study avoided the use of certain grammatical markers as they perceived these markers as being too humbling even when it was sociolinguistically appropriate to use them. Similarly, several women in Ohara's study resisted using a high-pitched voice as they felt it portrayed a "cute" feminine image at odds with their own self-image. Gender may also constrain the level of access that learners have to L2 use opportunities (Kouritzin, 2000). For example, L1 gendered cultural norms may limit women's access to ESL courses, as well as opportunities for L2 use.

Social identity has also been the focus of several strands of research in SLA. One strand investigates the use of L1/L2 pronunciation features as social marking while another strand has focused on how learners construct or resist developing a viable L2 identity. Both of these strands have been investigated under the framework that identity is expressed via the use of different L1/L2 linguistic markers. L2 speakers may selectively choose to use

L1 or L2 features to signal either an L1 or an L2 identity, ethnic affiliation, or both; in work on ethnic affiliation among French-Canadian learners of English, Gathbonton (1975) found that the use of English interdental fricatives was correlated with the learners' ethnic identity. Even learners with a young AOA may use L1 features for social marking if they have strong connections to their L1 community and extensive use of the L1. It has also been found that the extent and type of social networks, symbolizing extent of acculturation to and affiliation with the L2 culture, may be connected with overall L2 pronunciation accuracy as well as the degree of usage of particular L1 or L2 pronunciation features. Lybeck (2002) found that her participants' use of either a Norwegian L2 /r/ or English L1 /r/ was connected with their level of acculturation. These findings indicate that learners may actively use particular L2 features to signal an in-group identity or they may resist using particular L2 features, preferring to use L1 social markers, to either resist constructing an L2 identity or to retain an L1 identity. As all of these examples illustrate, identity is also crucially related to motivation, willingness, and openness toward communicating in the L2.

Recent research on social identity has focused on "passing" (Piller, 2002), which refers to the use of "stereotypical features characteristic of a particular variety in order to pass" as a native speaker of that variety (p. 193). As Piller suggests, the rationale for passing may not only be the wish to be perceived as a native speaker of the L2, but also to hide the L1 background possibly to avoid being stereotyped. It is a short-term "performance" or act of identity that is not possible to sustain for a longer period of time. Research by Moyer (2004) found that the L2 speakers of German in her study at times avoided using features of the L1 and used L2 features specifically to try to "pass" as native speakers of the L2. Trying to "pass" as a native speaker or performing L2 culture via the use of social markers may not always be welcomed by members of the L2 culture if they perceive the speaker is not a rightful member of that culture, as Lo's (1999) research on Chinese American and Korean American men has found. One of the Chinese American men had an extensive Korean peer group and had learned to speak L2 Korean via this network. However, his use of Korean was rebuffed by a Korean American, who perceived this "use of intimate in-group Korean American terms as an attempted appropriation of identity . . . [which] constitutes an unwarranted claim to insider status in a group he is not entitled to be a member of" (pp. 474–5).

In contrast to strategically employing features in order to "pass" as an inside member of the L2 culture, speakers may also avoid using particular features of the L2. As research by Siegal (1996) and Ohara (2001) shows, resistance to the use of L2 features may not be due solely to the desire to retain an L1 identity, but may instead be a rejection of the L2 identity that the use of the L2 features signals. In both studies, the women resisted using linguistic features (grammatical markers in Siegal's study and a high-pitched voice in Ohara's) as the use of these features symbolized a femininity identity in Japan that the L2 speakers perceived to be "too humble" a stance or "too silly" or frivolous (Siegal, 1996, p. 363).

Finally, research has also indicated that confidence in using the L2 helps learners to construct a viable L2 identity, which in turn helps them become "audible" (Miller, 1999) in the L2. In her research on immigrants to Australia, Miller (1999) found that learners who saw themselves as "rightful" speakers of English had the confidence to actually speak English when they moved from an English as a second language to a mainstream high school. Moyer's (2004) research on immigrants to Germany also found that confidence in using the L2 was the major determinant of the learners' ability to develop a viable L2 identity and social networks.

L2 speakers can also be active agents in targeting a particular variety of the L2. As Beebe (1985) states, L2 speakers are not "passive recipients of comprehensible input or incomprehensible input from native speakers (NSs) but [are] active participants in choosing the target language models they prefer and thus acquiring 'the right stuff' according to their

values" (p. 404). Research in this area assumes that learners "understand that their speech community is not homogeneous, that they are exposed to many varieties of English, and that they [sic] can make choices among these varieties" (Goldstein, 1987, p. 418). The findings from research in this area indicates that a particularly variety of the L2 may be targeted by learners based on peer group contacts, social class, gender, and geography.

The effect of the interlocutor on the pronunciation of L2 speakers has also been investigated. This research has typically been framed under the speech accommodation theory (SAT), developed to explain style shifts during interactions and the motivations for these shifts (Beebe & Giles, 1984). It has been found that both children and adults may vary their L2 use both in terms of amount of talk and use of L2 grammatical and phonological markers based on their level of identification with their interlocutor. In specific, learners may diverge or converge linguistically from an interlocutor who is a member of the L2 culture in order to show L1 ethnic solidarity (divergence from the interlocutor) or distinctness from the L1 group (convergence to the interlocutor).

In summary, there is a wide range of social influences on learners' acquisition of the L2. How the learner reacts to these influences is perhaps the most important and compelling aspect of this research. Findings indicate that far from being passive recipients of their language learning environment, learners actively choose, reject, and manipulate the use of L2 features in order to retain and develop viable L1/L2 identities which may be linked to gender, ethnic affiliation, perceptions of being a rightful speaker of the L2, and the level of affinity with the interactant, the language, and the culture, and so forth. Motivation for learning the L2—and its symbiotic relationship with identity—may also influence how learners react to their L2 environment. These findings have implications for future research in areas such as motivation and attitudes as well as language dominance and language shift as the learner eventually either shifts to the L2 (depending on AOA, LOR, and other social influences) or remains effectively an L2 speaker with a limited social and linguistic range. These strands bear investigation in future research on the effect of social influences on L2 speech acquisition.

Social Networks in Second Language Acquisition

NAOMI KURATA

Some people believe that one of the best ways to learn an L2 is to make friends with native speakers and to communicate with them using the language. There are, in fact, a significant number of studies that highlight the importance for students of moving beyond the classroom and participating in social interactions in the L2 in real-life situations (van Lier, 1996; Savignon, 1997). The possible benefits of out-of-class interactions with native speakers include enhancing learners' sensitivity to the target culture and increasing their self-confidence as well as willingness to use the L2, which, in turn, has a positive effect on L2 learning processes (Archangeli, 1999; Yorozu, 2001). However, few of these studies examine the social contexts in which such opportunities are constructed, and many seem to assume that as long as contact with native speakers is available, L2 learning and use will be unproblematic. As Neustupný (1987, p. 7) rightly maintains, there will be no practice and no learning unless language learners can find speakers of the L2 who agree to communicate with them. One of the principal ways to find such speakers in out-of-class contexts is through the learners' personal social networks.

Linguistic behavior occurring within speakers' social networks has been one of the major concerns in the field of sociolinguistics. Despite the increasing importance of concepts of social networks in this field as well as in other disciplines, learners' social networks in SLA settings have received little empirical attention to date, compared to network research relating to other sociolinguistic topics (Preston, 1989; de Bot & Stoessel, 2002). This entry will introduce some major theories of social networks and the significance of some concepts from them, and then discuss how the concepts have been applied to SLA.

Definitions of "Social Networks"

A great number of researchers have studied different types of social networks in a variety of disciplines, and, in turn, have defined these types of networks in different ways. As Barnes (1969, p. 53) explains, perhaps owing to the diversity of contexts in which the idea of a network has been applied, there is considerable confusion in the literature. A number of studies, for example, focus on communication and use the term "communication networks" (Rogers & Kincaid, 1981). On the other hand, sociolinguists who study networks are often concerned with the relationship between linguistic variations and speaker connections, and use terms such as "social networks," "personal networks," and "relational networks." Milroy (1987, p. 178) defines "social network" as "the informal social relationships contracted by an individual." Preston (1989, p. 152), on the other hand, explains that the number and type of relations an individual has to others compose his or her "network"; groups of such interrelated individuals are described as "social networks."

The diversity of these terms used in network studies is partly related to types of network analysis. According to Schensul, LeCompte, Trotter II, Cromley, & Singer (1999), there are three major contemporary approaches to networks as follows: ethnographic network mapping, ego-centered or personal network research, and the examination of full relational

Figure 1 Ego-centered network

social networks. The first approach uses ethnographic field research methods to describe the most common groups found in a culture. Studies based on the second approach describe index or focal individuals (often called “egos”) and all of the people (sometimes called “alters”) whom these focal individuals identify as members of their personal networks. More specifically, ego networks are defined as the ties of ego to alters located in his/her first order zone (those he/she actually knows) as well as the ties among the alters in this zone (see Boissevain, 1974) (see Figure 1). In this figure, the two members that are connected by a solid line know each other and connections to other individuals through the first order zone contacts (Alters 4, 5 and 6) form a layer of the second order zone. Lastly, the third approach requires the researcher to identify a naturally occurring social network and to examine the relationships among, and between all of the members of the network. The second approach relating to “personal network research” has been most commonly applied in SLA research, which is generally interested in the language development of individual learners. This is partly because this approach allows us to collect highly descriptive data about individual learners’ social networks from their point of view and to explore the relevance of these networks to L2 use and learning.

Significance of Social-Network Approaches and Major Theories

As mentioned above, network research has gained importance in a variety of academic fields. This is because concepts of networks allow us to expand our knowledge about the ways in which humans think, behave, and organize their daily lives within their own personal cultural context. Kim (1988, p. 107), for example, claims that network analyses enable us to find out emergent patterns of interpersonal communication behavior by examining the structure and contents of relational networks. Milroy (1987, p. 174) maintains that network concepts are a valuable tool of sociolinguistic analysis because these concepts are not limited by intercultural differences in economic or status systems. She also highlights the major contribution of network concepts to analysis of the manner in which individuals utilize the resources of linguistic diversity available to them. Furthermore, some other researchers claim that classic sociolinguistic factors, including gender and educational level, only give half of the picture about the social interactional mechanisms that enable speakers to maintain or change their language behavior whilst social-network concepts are useful in providing more complex and probably plausible explanations about these mechanisms (Raschka, Li, & Lee, 2002, pp. 22–3). Here, change of language behavior includes not only language shift/loss but also language acquisition. Regarding communicative competence as a situated phenomenon, Smith (2002) likewise argues that social-network approaches are an ideal tool to study this competence because the approach

enables us to investigate multiple, relevant discursive contexts in speakers' personal networks.

Social networks can be analyzed in depth using a wide variety of techniques and analytical variables. Which of these techniques and variables are utilized and how they are applied are different in different studies, depending on their aims, types of data, settings, and so forth. In L2 learning settings, social-network theories that originally derived from empirical research in sociolinguistics as well as anthropology have been mainly utilized. One measure of network type is "multiplexity," that is, the diversity of social relations between individuals. A relation between two persons that is based on a single role relation (for example, neighbor or workmate) is referred as "uniplex" or "single-stranded," whilst a relation that covers many different roles (for example, workmate, friend, and neighbor) is termed "multiplex" or "many-stranded" (Boissevain, 1974). Multiplex relations seem to be stronger than uniplex ones, in the sense that one role relation reinforces others. In addition, Boissevain (1974) hypothesizes that there is a greater accessibility and response to pressure between two persons with a multiplex relationship than those with a uniplex relationship and that people who have multiplex relations will be more intimate (in the sense of friendly and confidential) than those who have uniplex relations.

Another variable relevant to network research in SLA is "frequency of interaction." This variable is a result of the quality of the relation in that it often reflects multiplexity of shared roles and the nature of the elements exchanged (Boissevain, 1974). However, this does not apply to all the relations, as two persons may not necessarily think that their relation is important, even if they meet quite often. In other words, frequency of interaction can be, but is not necessarily, an index of the investment of the persons in the relationship.

"Density" is also an important criterion that measures the number of connections among people who are linked to the focal person. It is, therefore, an index of the potential communication between parts of the network and thus of the quantity and types of transactions that can be exchanged (Boissevain, 1974). "Clusters" are segments of networks which have a relatively high density (see Figure 2 which shows two clusters: Clusters A and B linked via ego). The persons who form clusters are more closely linked to each other than they are with other members of the network. Clusters are often recruited from different activity fields.

These are some of the social-network notions that have been drawn on in the SLA research from a network perspective. The next section will outline some major findings of this research and suggest how these notions are related to L2 learning and use.

Figure 2 Clusters A and B linked via ego

Research Into the Links Between Social Networks and SLA

Two studies that are directly concerned with the relationships between the characteristics of social networks of immigrants or expatriates and L2 language learning have been undertaken by Smith (2002) and Wiklund (2002). Wiklund (2002) examined the social networks of bilingual (immigrant) adolescents in Sweden, and assessed the role of networks in their development of L2 proficiency and school success. Unlike the other studies that will be introduced below, Wiklund does not examine the comprehensive personal networks of these participants but only a subset of their three best friends from each of three groups: own ethnic group, Swedes, and an ethnic group other than their own and Swedes. By correlating the network scores of each participant, including density, multiplexity, and frequency of interaction, with his/her proficiency in Swedish, the researcher highlights the importance of differently oriented social networks in the development of L2 proficiency. More specifically, the highest network scores were reached by those whose networks were oriented equally toward Swedes and groups other than their own. In addition, these participants as well as those whose networks were mainly oriented toward Swedes tended to perform better in Swedish. Considering network scores as a sign of sociality, which is likely to promote L2 use, the researcher explains that in these two types of networks negotiation of meaning occurs, which facilitate SLA.

Smith (2002), on the other hand, presents a multiple case study of US expatriates living in Southeast Asian cultures. Utilizing a modified version of the social support network inventory and oral situation test (OST) as a research instrument, the researcher examined the participants' comprehensive personal or egocentric social support networks and explored the correlation between their network properties and L2 communicative-competence measures. Similar to Wiklund (2002), Smith found that "frequency of interaction with hosts" and "percentage of host nationals in the network" are positively related to communicative competence. In addition, Smith found a weak correlation between the size of the networks and competence. Smith also claims that the factors of "density" and "closeness" may negatively affect the informants' communicative competence since dense networks, where close relationships are often formed, may seclude the expatriates enough to prevent exposure to new lexical items and sociolinguistic situations, thereby impeding language learning.

Both Smith (2002) and Wiklund (2002) were thus interested in the correlations between the characteristics of social networks and L2 proficiency. In order to measure this proficiency, they required their informants to produce written texts or to take oral tests to assess their proficiency. Given an increasing awareness of contextual and social aspects in language learning research, it is also important to investigate how actual interactions with network members influences SLA. Tarone (1997) suggests that the way native speakers and learners behave in a formal, task-oriented context cannot be assumed to be the way they behave in the real world and highlights the necessity to study L2 learning processes in natural settings for everyday communication.

Kurata's (2004a, 2004b) research takes up in part Tarone's (1997) suggestion of the significance of examining authentic interactions in natural settings. Her research presents a case study of the social networks of upper-intermediate level language learners studying Japanese at an Australian university. Dealing with a wide range of data, including interactive discourse occurring in naturalistic environments as well as introspective reports and interviews, the study examined the relationship between the learners' networks and SLA in their home country. Utilizing Boissevain's (1974) criteria for network analysis, the researcher compared the characteristics of the informants' current networks with those that existed prior to their in-country experiences. In addition, her study applied the framework of communicative competence developed by Neustupný (1987) and sociocultural

theory to analyze the informants' language learning in their actual interactions within their networks.

The results of Kurata's research indicated that a number of characteristics, such as "multiplexity," the variety of backgrounds of their network members, and the close relationships between the informants and their network members were probably related to the raising of their nonlinguistic as well as linguistic awareness. Moreover, she found that the learners of Japanese in this research made significant investments in interaction in "clusters" (segments of networks which have relatively high density), and, in turn, they were exposed to Japanese culture as well as Japanese language usage in natural settings. It was argued that this exposure would facilitate opportunities for L2 learning. Furthermore, the analysis of some naturally occurring interactions within the learners' social networks revealed that these interactions provide a very valuable source of comprehensible input and output, which possibly leads to language learning.

As regards Japanese learning in host-country settings, there are a number of case studies that have examined the links between learners' social networks and L2 learning. The concept of network was first employed in this setting by Haruhara (1992), who investigated "networking strategy." In this study, Haruhara stressed the importance for learners to consider their daily life situations as learning. Subsequent to Haruhara's study, the Committee of Network Research in the Japanese Language Education Society carried out research into learners' Japanese language acquisition from a network perspective (Nihongo Kyooiku Gakkai Nettowaaku Choosa Kenkyuu linkai [The Network Research Committee of the Japanese Language Education Society], 1997). Their research includes several case studies that focus on the effect of learners' networks on Japanese language acquisition, the learners' evaluation of their networks, and the linkage between their learning strategies and the maintenance of their networks. The participants of these studies were foreign residents of Japan with a variety of backgrounds, such as refugees, foreign wives with Japanese husbands, overseas students, and so on. The researchers employed ethnographic methods, for example, participant observation, and interviews with learners, their partners, and their teachers.

The results of these case studies revealed some important factors that facilitate Japanese learning, including learners' active participation in networks where they can engage in a variety of activities and can develop mutual and close relationships with native speakers, and the existence of key persons who support the establishment and the maintenance of networks or encourage learners to participate in different networks. On the other hand, there are a few negative factors affecting Japanese learning. A number of participants in this research believed that networks with co-nationals hindered them from establishing networks with native speakers and impeded the improvement of their Japanese skills. Moreover, some other cases in this research demonstrated that a lack of active participation in networks with either co-nationals or Japanese native speakers resulted in a lack of information about Japanese learning and of opportunities to communicate with native speakers.

Other SLA Research in Social-Network Contexts

Within English as a foreign language (EFL) settings, two more recent studies explored the relevance of learners' social networks to their L2 learning (Ferenz, 2005; Palfreyman, 2006). Ferenz (2005) investigated the types of social networks in which six graduate students at an Israeli university discussed their L2 disciplinary writing tasks and the impact of these networks on the development in their L2 academic literacy. Ferenz identified two types of social networks, namely, academic-oriented and nonacademic-oriented networks. Her

analysis further indicated that the members in the former social networks assisted the students in promoting their L2 advanced academic literacy, among other things, by developing their disciplinary knowledge as well as modeling L2 literacy practices. The students' nonacademic-oriented social networks, in contrast, were claimed to promote general literacy skills. Ferenz also suggests that students develop academic-oriented networks in order to pursue academic identity as well as academic goals whereas nonacademic social networks reflect the students' other types of identities and goals, such as those of a professional nature. Ferenz finally recommends that students' identities, goals, and access to supportive social and academic environments should be taken into consideration for the learners' L2 literacy development.

Focusing on social and material L2 resources outside formal learning settings, Palfreyman (2006) examined how the use of these resources by female university students in the United Arab Emirates was shaped by social contexts. Based on an online survey as well as interview data, Palfreyman found that the students utilized a wide variety of resources in these settings to practice L2 as well as to clarify their understanding of the language. Viewing social networks as a key concept in understanding the ecology of social resources, Palfreyman claimed that gender and perceived expertise in English affected the students' use of these resources. Relatively high English proficiency of the students' older sisters, for example, was found to contribute to an available source of expert help. Palfreyman thus suggests that social networks influence the accessibility and use of social resources. In addition, the findings demonstrate that the students themselves acted as sources of English expertise, which, in turn, might strengthen their status, social identity, or both in their family as well as community.

A significant multiple-case study concerned with the effect of social networks on academic literacy socialization in an ESL setting was conducted by Zappa-Hollman (2007). Combining the notions of social networks (Milroy, 1987) and communities of practice (Lave & Wenger, 1991), she proposes the concept of "individual network of practice" (INoP). This concept is defined as "all the social ties of any given individual, whether weak/distant or strong/close, relevant to the phenomenon under study" (Zappa-Hollman, 2007, p. 21). The researcher found INoP useful as an analytical construct to examine the nature and impact of six Mexican exchange students' interpersonal relationships on their L2 academic literacy development and performance at a Canadian university. More specifically, one of the participants' (female) investment in INoP ties provided her with affective and academic returns, both of which were positively related to her socialization into the academic culture of her host university, including its attendant literacy practices. In addition, this study reveals that the network members from whom this participant mostly received such returns were characterized by multiplex ties, such as friends, classmates, and sometimes also team mates at university.

Although the above brief review of the literature has provided insights into the links between learners' networks and L2 learning, it tells us little about the processes of how learners construct opportunities for L2 use and learning in their natural interaction within their social networks. There are, however, an increasing number of studies that discuss the issues of learners' access to such opportunities from poststructural perspectives. They argue that although the learners actively shape their own L2 use and L2 learning experience, they can construct such experiences only to the extent that their sociocultural contexts, including social networks, allow them to do so, and that the construction of this experience is pertinent to that of the learners' identity. From a social network perspective, the importance of the interaction between social networks and speakers should be stressed. In other words, social networks influence speakers, but speakers themselves also choose and influence social networks.

Kurata's more recent study (2007a, 2007b, 2010, 2011) examines how opportunities for L2 use and L2 learning are socially constructed in foreign-language learners' social networks. Through triangulation of ethnographic data, including interactive discourse occurring in natural social settings and interviews, and utilizing sociocultural theory alongside of other poststructural perspectives, Kurata pursued a holistic approach for exploring major factors that affect the construction of these opportunities, including individual, interpersonal, and larger societal/institutional factors. She also applies Auer's (1984, 1988) approach to code switching and transfer in order to conduct an in-depth examination of L1/L2 selection at a micro level.

The findings of Kurata's study reveal that the students in her study were able to establish social networks in which native speakers of Japanese were participants on an equal footing, such as friends, peers, or both. More importantly, the study also indicates that the same students sometimes have difficulty gaining access to informal interactions in Japanese in these networks, in particular, in the university domain. This difficulty can be attributed to various factors, including the learners' history as an L2 learner/user, shared or divergent goals of the interactants, and the dominance of English in the community. However, the analysis of processes of L1/L2 selection and negotiation in their interactions demonstrates that access to L2 appears to be mediated by both micro- and macrolevel factors, such as strength of signaling the learner's preference for L2 and norms in the community where the learner is situated.

As regards opportunities to learn L2, in noninstructional settings there was a general disinclination for linguistic correction and assistance. A possible conflict between the interactants' role as a communicator and that as a novice/expert user of L2, among other things, may contribute to this. These settings, however, seemed to offer opportunities for the learners to utilize available interactional resources and to possibly further develop relevant competence as well. In the case of semi-instructional settings, including language exchange partnerships, the native speaker's provision of assistance with regard to lexical knowledge represented the most frequent overt type of learning opportunity, but there were other opportunities that were not so obvious.

The general picture that emerges from the literature review undertaken above is that concepts of networks have provided a powerful analytical tool for research in a diverse range of L2 learning contexts, such as host-country versus home-country settings, learners from minority populations versus foreign-language learners, communicative competence versus academic literacy, and so forth. The concepts also allow SLA researchers to analyze an individual learner's personal networks in depth, which, in turn, help them to explain important parts of the social structure that facilitates or constrains L2 use and learning. Furthermore, as shown in the above studies, the social-network approach allows for both quantitative and qualitative analyses. This approach thus enables both examinations on a larger scale and detailed case studies at the same time. Indeed, as de Bot and Stoessel (2002) claim, without examining qualitative data, the quantitative component of network research cannot be evaluated fully by itself.

Future SLA Research From a Social-Network Perspective

The above network-related research in SLA settings has thus contributed information to our current knowledge concerning the way people learn an L2 outside educational settings. However, given that numerous SLA studies suggest that L2 social interaction is a valuable source of L2 learning, this research area should attract more empirical attention in the future. In particular, with the spread of the Internet, students now have the opportunity to use an L2 outside of the classroom in many more ways than were previously possible.

However, researchers have only recently begun to explore how the new technologies, including online chat and social networking services, affect the maintenance and development of learners' informal social networks with L2 speakers as well as their actual language use and L2 learning within these networks (Pasfield-Neofitou, 2007a, 2007b). Pasfield-Neofitou (2007a, 2007b), for example, examines the features of intercultural Internet chat between learners of Japanese and their Japanese friends and how these learners use this medium as an opportunity for communication and for informal language learning. She found that chat was a vehicle for cementing or continuing social interactions between some learners and their Japanese friends despite their geographic separation. In terms of L2 learning, her analysis revealed that repair was more frequent when learners had a primary goal of language learning rather than social interaction, and that the visual nature of text-based chat seemed to facilitate repair. Intercultural online communication in L2 learners' informal social networks is thus an important area for future investigation.

Social, Dynamic, and Complexity Theory Approaches to Second Language Development: Overview

AMY SNYDER OHTA

Social, dynamic, and complexity approaches to second language acquisition (SLA) take a process-oriented view of language. In general, this view sees process and product in a dynamic relationship, always in process, always in flux, always changing just as individuals are always changing across the lifespan (Lantolf & Thorne, 2006; Larsen-Freeman & Cameron, 2008). Along with using the term *acquisition*, which is in wide use in the field of SLA, but implies a static view of language, the researchers represented in this section often prefer the term *development*, which better reflects a dynamic, variable, process-oriented view of how people develop facility in languages beyond their native language(s). In the remarks here, intended to provide an overview of the Social, Dynamic and Complexity Approaches to Second Language Development section, as well as within the entries of this section, the terms *acquisition*, *learning*, and *development* are all used. Generally what is meant, both in entry titles and in texts describing L2 research, is a dynamic, process-oriented view of language, acknowledging that human facility with language is always in motion and always changing. Though the word *acquisition* is not always the best word to portray this view of language as process, for the sake of simplicity, the term SLA is often used throughout the section.

The title of this section contains three important terms: *social*, *dynamic*, and *complexity*. *Social* refers to social interaction. It also refers to the development of human language and higher mental processes as a social interactive process, one that not only results in human development but also shapes the formation of human cognition and personality such that human functioning on all levels, including the level of thought retains a social interactive character. In this section, this social view of human cognition is represented by scholars using sociocultural theory (SCT), a framework grounded in the work of Lev Vygotsky and his colleagues, as well as other sociocognitive approaches. Scholars working with such approaches also see language development as *dynamic* and *complex*. That is, as characterized by change, and as involving multiple factors. The latter two terms relate most strongly to another set of approaches to SLA: dynamic systems theory (DST) and chaos/complexity theory (CCT). While these title words most strongly relate to these approaches to SLA, they also evoke other approaches and topics in the discipline that are covered in this section. In other words, this section is not theory- or approach-specific, but the entries here are included based upon the broad principle that the areas of study represented are based in a view of language learning and development that is simultaneously culturally embedded, socially interactive, dynamic, and complex.

Language development is integrated with human social and cognitive development such that children not only develop language, but through these processes they also influence the social groups and societies of which they are members (Ochs, 1988). Second language development is arguably even more complex, as it involves the re-mediating of mind to function using a new set of cognitive tools. The field of second language acquisition has grown more and more diverse as researchers have grappled with this complexity. While

early studies in the field tended to assume cause-effect epistemologies, seeking to understand variables that were necessary and sufficient for SLA, researchers today who embrace the cognitive, psychological, social, societal, and historical complexity of L2 development are working to better understand a wide range of L2 developmental processes. The diversity of SLA studies is such that this encyclopedia devotes a number of sections to SLA and related areas of inquiry: the present section, Social, Dynamic, and Complexity Approaches to Second Language Development, and four other sections, Cognitive Second Language Acquisition, Bilingualism and Multilingualism, Bilingual Education, and Language Teaching and Learning. In addition, second and foreign-language (L2) research is also covered in the sections Lexis, Phonetics and Phonology, and entries related to bilingualism and multilingualism are also represented in the sections Translation and Interpreting, Lexis, Literacy, Qualitative Methods, and Quantitative Methods.

Social, Dynamic, and Complexity Approaches to Second Language Development contains 34 entries. These entries relate to a range of areas of inquiry, both new and old in the field of SLA. Entries relate to L2 development processes, classroom language learning (and beyond), approaches to SLA, and learner characteristics.

L2 Developmental Processes

While all entries in this section relate to developmental processes, there are a number that direct our attention toward particular areas of L2 development. How does an individual's facility in the L2 develop over time? How does a learner construct a linguistic system for the language being learned? The entry *INTERLANGUAGE* describes sociolinguistic variationist research applied to SLA in an area of inquiry that dates back to the early days of the field. There are also entries considering development of particular L2 skills, including writing development (see *WRITING DEVELOPMENT IN SECOND LANGUAGE ACQUISITION*), and oral and written narrative development (see *NARRATIVE DEVELOPMENT IN SECOND LANGUAGE ACQUISITION: ORAL AND WRITTEN*). Use of gesture (see *SECOND LANGUAGE ACQUISITION AND GESTURE*) when speaking a second or foreign language is a newer area of inquiry in SLA that is also included here.

Language Learning in the Classroom and Beyond

Facility on second and foreign languages develops in a variety of settings. The encyclopedia has an entire section devoted to classroom settings—the section entitled Language Teaching and Learning. The present section also touches on this area, investigating classroom research (see *CLASSROOM RESEARCH IN SECOND LANGUAGE ACQUISITION*), teacher beliefs (see *BELIEFS IN SECOND LANGUAGE ACQUISITION: TEACHER*), and learner beliefs (see *BELIEFS IN SECOND LANGUAGE ACQUISITION: LEARNER*) in SLA. The entry on praxis (see *PRAXIS AND SECOND LANGUAGE ACQUISITION*) relates to the work of language teachers themselves and the integration of theory and practice. Other entries also relate to the classroom setting, such as the entries devoted to the zone of proximal development (see *ZONE OF PROXIMAL DEVELOPMENT IN SECOND LANGUAGE ACQUISITION*) and collaborative dialogue (see *LANGUAGE: COLLABORATIVE DIALOGUE AS A SOURCE OF SECOND LANGUAGE LEARNING*). The entry on *LANGUAGE SOCIALIZATION IN STUDY ABROAD* considers how language develops both in classroom (tutored) learning and untutored learning in various settings in the broader community. Whether abroad or at home, language-learning opportunities are deeply related to learner involvement in L2 social networks (see *SOCIAL NETWORKS IN SECOND LANGUAGE ACQUISITION*).

Approaches to SLA

A number of entries in this section relate to particular approaches to SLA, or to particular research methodologies. Theoretical systems covered here are sociocultural theory (SCT) (see RESEARCH METHODS AND SOCIOCULTURAL APPROACHES IN SECOND LANGUAGE ACQUISITION), dynamic systems theory (DST) (see DYNAMIC SYSTEMS THEORY APPROACHES TO SECOND LANGUAGE ACQUISITION) and chaos/complexity theory (CCT) (see CHAOS/COMPLEXITY THEORY FOR SECOND LANGUAGE ACQUISITION). The last two are often considered together. The section also contains entries related to qualitative approaches to studying SLA including entries on ethnographic approaches (see ETHNOGRAPHIC APPROACHES TO SECOND LANGUAGE ACQUISITION RESEARCH), narrative approaches (see NARRATIVE APPROACHES TO SECOND LANGUAGE ACQUISITION), and sociocognitive (see SOCIOCOGNITIVE APPROACHES TO SECOND LANGUAGE ACQUISITION) approaches to SLA.

Some approaches to SLA are further developed through additional related entries. For example, there is an entry on variability in the DST approach (see VARIABILITY IN A DYNAMIC SYSTEMS THEORY APPROACH TO SECOND LANGUAGE ACQUISITION) and one on COMPLEXITY IN MULTILINGUAL SYSTEMS, which draws upon both DST and CCT. These approaches are closely linked with neurobiological approaches to SLA as well, and this section contains an entry on the NEUROBIOLOGICAL FOUNDATIONS FOR SECOND LANGUAGE ACQUISITION, as well as one exploring NEUROBIOLOGY AND MOTIVATION IN SECOND LANGUAGE ACQUISITION and development.

Other entries also relate to this framework, which is grounded in the cultural-historical psychology of Lev Vygotsky (see VYGOTSKY AND SECOND LANGUAGE ACQUISITION). Some of these relate to Vygotsky himself or to key concepts or constructs in sociocultural theory: INNER SPEECH IN SECOND LANGUAGE ACQUISITION, INTERNALIZATION IN SECOND LANGUAGE ACQUISITION: SOCIAL PERSPECTIVES, PRIVATE SPEECH IN SECOND LANGUAGE ACQUISITION, and the ZONE OF PROXIMAL DEVELOPMENT IN SECOND LANGUAGE ACQUISITION. Others concern concepts that are deeply related to sociocultural principles but use newer terminology, such as entries on praxis (see PRAXIS AND SECOND LANGUAGE ACQUISITION), languaging/collaborative dialogue (see LANGUAGING: COLLABORATIVE DIALOGUE AS A SOURCE OF SECOND LANGUAGE LEARNING), and DYNAMIC ASSESSMENT IN SECOND LANGUAGE ACQUISITION. There are also entries discussing research methods in SCT (see RESEARCH METHODS AND SOCIOCULTURAL APPROACHES IN SECOND LANGUAGE ACQUISITION) and the METHODOLOGICAL FOUNDATIONS OF SOCIOCULTURAL THEORY. These entries, taken together, provide an overview of the work of L2 researchers in this area of neo-Vygotskian research. There is also an entry focusing on how L2 researchers apply the work of Vygotsky's contemporary Bakhtin (see BAKHTIN AND SECOND LANGUAGE ACQUISITION) to SLA.

Individual, Learner Characteristics

Individual differences is an area of interest in SLA that has produced a great deal of research (Robinson, 2002). Despite the term "individual" differences implying that such research must focus on particularities of particular learners, early research in this area tended to consider groups of learners, conducting research using factor analysis and other quantitative approaches. Researchers coming from social, dynamic, and complexity approaches, however, have worked to place the individual at the center of such research. A number of entries in this section, therefore, strongly relate to individuality and learner characteristics, including entries on motivation (one on MOTIVATION IN SECOND LANGUAGE ACQUISITION in general, and one on NEUROBIOLOGY AND MOTIVATION IN SECOND LANGUAGE ACQUISITION), social networks (see SOCIAL NETWORKS IN SECOND LANGUAGE ACQUISITION),

4 SOCIAL, DYNAMIC, AND COMPLEXITY THEORY APPROACHES

gender (see GENDER AND SECOND LANGUAGE ACQUISITION), identity (see IDENTITY AND SECOND LANGUAGE ACQUISITION), agency (see AGENCY IN SECOND LANGUAGE ACQUISITION), and then also language play (see LANGUAGE PLAY IN SECOND LANGUAGE ACQUISITION) in SLA. In addition, focus on individuals is strong throughout the section, as many of the studies use methodologies that focus on careful study of individual learners.

Conclusion

This brief overview has served to outline the areas covered in this section, as well as to touch on other parts of this encyclopedia with entries related to social, dynamic, and complexity approaches to SLA. However, in the brief space allotted to this introduction, much has been omitted. The reader is encouraged to explore this encyclopedia, as there is much related work outside of the realm of SLA as well. We are most fortunate to now have such a monumental work in the field of applied linguistics, to provide students and professionals with a stronger grounding in this field both as it relates to SLA and to language issues across society.

Societal Pragmatics

JACOB L. MEY

Introduction: Why “Societal Pragmatics”?

Given that pragmatics, by definition, is social, one could legitimately raise the question: Why is it necessary to talk about “societal pragmatics”? Implicit in this question is a preliminary assumption, which leads us to a further, more fundamental question: What do we mean by saying that pragmatics by definition is social, and why is this a “given”?

In the course of the last century, the study of language (also called “linguistics”) has moved away from the classical paradigm, in which the study of language was either mainly *historically* oriented (where do languages come from and how are they related?), or focused its interest on linguistic *structures* (how do languages go about organizing their expressions?). The first question was typically the object of “historical grammar,” as it used to be called; the second question belongs in the realm of syntactic studies, which for a great part still are understood by many as the primordial area of linguistic interest. What is called the “pragmatic turn” in linguistics may thus be described as a “shift from the paradigm of theoretical grammar (in particular, syntax) to the paradigm of the language user” (Mey, 2001, p. 4).

But what is such a “paradigm of the user” all about? Here, our question must naturally direct itself at what the users *do* with their language, or “how they do things with words,” as expressed by John L. Austin in the title of his famous posthumous treatise (1962).

The Importance of the User

The idea of a user naturally presupposes the idea of *use*: “use is what a user does.” When it comes to language use, we can easily observe that language is used primarily for the purpose of communication. The business professionals concluding a deal communicate their preferences and conditions by using language. Lawyers use language to communicate their viewpoints to the judge and the jury, while advertisers express themselves through language when providing suggestive or useful information about their products. Even on the domestic front, partners agree or disagree, quarrel and make up again, using the linguistic resources at their disposal. And when it comes to education, communicating knowledge and checking feedback on provided input would be impossible without language.

But communication should not be thought of as a one-way or two-way street, with somebody (the sender) throwing out some message and somebody else (the receiver or receivers) catching it and retuning it like one does a volleyball serve. The idea of language users acting like “talking heads” (as is often proposed in initial chapters of introductory linguistics textbooks) is not only limiting but downright misleading. While it is true that communication mainly happens by means of language, language is certainly not the last word. And society should be taken seriously when we are dealing with communication. The “one-way street” is not only limited and limiting, but it basically leads nowhere if it isn’t placed in its proper context: society.

As to the users of language, as social beings they use language and communicate strictly on society’s premises. Society not only controls access to language but it enables its users

2 SOCIETAL PRAGMATICS

in their communicative activities. While pragmatics in general—as the study of the way humans use their language in communication—is based on society’s premises, societal pragmatics explicitly invokes those premises and inquires how they affect our language use. Hence, while “pragmatics is defined as the study of language in human communication as determined by the conditions of society” (Mey, 2001, p. 6), societal pragmatics emphasizes the social conditions under which we live and use language, and tries to determine in what specific ways these conditions or respectively facilitate or obstruct, indeed, “make and break,” our use of language.

Society and Its Discontents

There are many ways of looking at society. Philosophers and economists of the “objectivist” obedience have considered society as an inevitable but hardly desirable way of going about our social business; for British economists of the 19th century, the ideal society was considered a kind of “night watchman”: a necessary, but not necessarily popular institution.

A more adequate, contemporary view of society is one by which the economic conditions under which we live are considered to be of decisive influence on the way we organize our social world, including the way we express ourselves in words and emotions. This view distances itself both from a strict economic determinism, by which social relations are thought to be exclusively materially bound, and from the view that our social relations exist between individuals in the first place, to be extended beyond the “two-way street” interaction alluded to above, to comprise a more extended give-and-take. There is a German proverb that says *Der Mensch ist was er isst* (“Humans are what they eat”). One could modify this to say “Humans are what they make”: the capacity of humans to produce useful things leads them to invest their mental and material energies in the object they have made.

Of Things and Words

Karl Marx was one of the first who focused on the special character of the human-made object as encapsulating human social relations in the shape of a *thing*: the “fetish,” as he called it. When the social relations of production and consumption in our society become measured by, even defined by, the marketing value of their outcomes, our social relations themselves, too, become “things.” But when this happens, we no longer see the processes that led to the production of useful goods, but only the end results, the marketable commodities. The value of the product is not measured in terms of the social relations that were necessary to produce it. Its only value is what can be expressed in terms of the market. As Marx states: “The value of a thing is the price it will bring” (Marx, 1954, I, ch. 1, sec. 1, n.7). The market is indifferent to the conditions of labor under which the marketable goods are fabricated; the outcome of the human labor is uniquely represented in the money value that the market allows one to charge for it.

As far as language is concerned, the “thing” character of the marketable product carries over to its linguistic expression: words become abstract value carriers that bear no relation to the conditions under which they were created. An expression like “welfare reform,” as currently used in many communities worldwide, has lost its connection to the context in which it was first launched: a desire on the part of a governments to limit its expenditures, without regard for those who were supposed to bear the brunt of the “reform.”

It is certainly no exaggeration to say that there are worlds of difference between the various uses of a term; yet all uses have in common the fact that they reflect (and often “mask”) the modes of thought and ideologies that were prevalent in the societal contexts

where they originated. Societal pragmatics sees it as its primary task to “unmask” manipulative use of language, and to set the record straight by connecting controversial and “masking” expressions with their proper contexts.

The next few sections will deal with another aspect of societal pragmatics: abuse—rather than use—of language. The concluding sections will address how a societal pragmatics may counteract the manipulative use of language by acting upon it in an emancipatory way, by “recontextualizing” the users, that is, placing them and their languages in their own, appropriate contexts.

Abusive Language

In every day usage, “abusive language” is thought to consist of vituperative words and expressions, as when we call people names, or diminish their dignity as humans by comparing them to low-prestige animals. In a broader context, the terminology we create for controversial natural and social phenomena often is abusive in that it puts the user in a double bind: thus, some of our leaders have been instructed to use a term like “climate change” in order not to offend their constituents, who may be shocked to hear that the “global warming” their own actions are actively promoting is the current ecological downturn’s real cause and name. A societal pragmatics should look for ways to express sensitive matters in such a way that we neither offend our listeners, nor discredit the integrity of our words.

Language and Sex

Other instances of abusive language frequently occur in the general area of language and gender and are often referred to under the common label of “sexist language.”

The British feminist linguist Dale Spender coined the expression “man made language” and used it as the title of an important early work on sexual discrimination by way of language (Spender, 1980). Her book wants to make us aware of the social oppression that is built into the common assumption that a male use of language is essential superior to a female use, where “male” and “female” are considered to be equivalent to, respectively, authority and submission. What’s more, the female members of society are often made “invisible” by the universal use of the male pronoun *he* and the general referring term for “humans” *man*. Much of this is, so to speak, built into the very foundations of one’s language. At times, we are able to remedy some of these grammatical incongruities, for example by not saying “he” when the person we refer to could be either male or female, but using a form like “he or she” (in writing, one could use “s/he”). The main thing is to be aware of the invisible oppression of one of the human sexes by omission or “erasure,” as it is now commonly called.

In all this, we have to realize that for tens of thousands of years the social conditions in which our species has lived have been dominated by males. In such an oppressive societal situation (see Mey, 1985, pp. 25–6), the powerful dominate the powerless, not only in material respects, but also regarding other, less tangible matters, such as the use of language. Becoming aware of this oppression is the first condition for engaging oneself actively on the side of the oppressed—first of all women, for whom the fact that “man” has made language is the very cause of their linguistic oppression. Every time we force ourselves to use a form like “she or he,” rather than the so-called generic “he” (supposedly covering both sexes), a little step is taken toward the realization of the fact that “man-made language” is an historical accident, not a natural condition which cannot be changed.

The presence of women in the world can be emphasized and protected through this small, seemingly insignificant shift in the language—and therefore, it is not useless or

in vain. The next sections will treat in more detail why, and how, an “emancipatory” view of social conditions should be part of any decent societal pragmatics.

Emancipatory Pragmatics

The term “emancipatory pragmatics” is an extension of what elsewhere I have called “emancipatory linguistics” (Mey, 1976, 1979, 1985, 1994, 2001, in press; see also Signorini, 2009). The first question to ask is what is meant by “emancipatory”? What or who emancipates, and from what?

The ancient Romans used the term to characterize the process by which a slave was freed from his or her bonds. The slave’s relation to the master (and metonymically, the slave him- or herself) was termed *mancipium*, literally a “taking by the hand”; when the slave gained freedom, in a legal process called *manumissio*, literally a “sending off from the hand,” this legal bond and the ensuing obligations were extinguished. When it comes to emancipatory linguistics, the term was originally intended to signify the freeing of the language users from the societal oppression as it was manifested in language. In the latter half of the 20th century, sociolinguists such as Basil Bernstein remarked on the fact that social origin often leads to societal inferiority in matters of education and use of language. The socially inferior were also underprivileged with regard to culture and the workings of democracy. An emancipatory linguistics was thought of as ideally serving the underprivileged, the “proletarians of the word,” and as such was seen as part of the social struggle. Especially in the realm of education, these thoughts were instrumental in various attempts to reform the curricula of the various levels of the educational system, in particular where the weakest recipients of instructional benefits were found: primary schools, not only back home but also in developing and “threshold” countries.

The Limits of Emancipation and the Need for Anticipation

Pragmatics is all about the use of language and the people who use language. Freeing them from the bondage of false beliefs and societal oppression is thus an appropriate task of a societal pragmatics that is true to the ideals of emancipation. But emancipation in and of itself is not enough: there is a life after emancipation. Pragmatics has a paramount role in the liberation of the users, but it must follow up the emancipatory process in sustained supportive action. In other words, in order to be successful, emancipation presupposes an *anticipatory* activity.

Such a task is not just confined to the here and now; we must look ahead, and this is where anticipation comes in. (My use of the term “emancipatory pragmatics” is inspired by what anthropologists such as Robert B. Textor have called “anticipatory anthropology,” described as “a disciplined effort to discover proactively what members of a human group want and what they fear, and what sacrifices they are prepared to take, toward realizing the former or avoiding the latter”; Textor, 2009, p. 21.) Since pragmatics is about the use and users of language, an emancipatory pragmatics *proactively* deals with how to use language in a nonoppressive, even liberating way. By looking ahead, rather than just confirming or critiquing the status quo, societal pragmaticists endeavor to proactively promote and create a language use that will prevent people from abusing the gift of language to their own egoistic ends. The task of such an anticipatory societal pragmatics is to foresee and prevent abuses of the kind that were mentioned earlier, and enable the users to counteract all sorts of abusive language before it starts being accepted as the normal way of dealing with the world and its inhabitants. In this way, an emancipatory societal pragmatics will be able to undo the negative effects of what I call “manipulative discourse.”

Manipulative Discourse

The term “discourse” is often used to characterize not just speech, but the ensemble of attitudes that people have vis-à-vis their “life world,” to use an expression dear to Ludwig Wittgenstein. Discourse not only manifests itself in language; it is handled and nurtured by language, specifically through the ways in which we express our ideological preferences linguistically. In this sense, discourse not only creates and recreates the social fabric on which it is predicated, but it also disposes us toward accepting the particular societal order that we happen to live under as universally valid and natural.

The discourse of manipulation can be thwarted by adopting a societally pragmatic stance, for example by practicing a (pro)active understanding of one’s adversaries. Other manipulative discourses that come to mind in the context of a societal pragmatics are embodied in the language of social oppression, of sexual discrimination, of (neo)colonialism, and so on. Recently, we have witnessed the rise of a specific “discourse of terrorism,” by which acts of violence are glorified as heroic deeds, and their perpetrators are lionized as “martyrs.” Among young immigrants living in the cities of the United States and Europe, a new attitude takes the discourse of terrorism as embodying their own resistance to global capitalism, their kinfolks’ fight for independence, and their own desire to improve their livelihoods (the populations of the inner cities of France and Britain may serve as egregious examples).

In order to turn back the wave of violence that is rolling in over our society, we need to redefine the mentality that is expressed in this discourse; but also, proactively and emancipatorily, we need to replace the language itself that is being used in the terrorist discourse. Why should a suicide bomber be called a martyr and not a mass murderer? Replacing the discourse of terror with a discourse of “doing no harm” (for instance as in the Gandhian tradition of *ahimsa*) is a first, and very necessary, step toward eliminating terrorism itself. A proactive discourse that propagates a societally pragmatic approach to these and other societal evils may point the way to ending abusive discourse, and emancipate us from the tyranny, not only of the language of evil, but of the social evils that are at the bottom of abusive language.

Anticipating the Future

A caveat is in order here. Anticipating a person’s needs can be used to manipulate him or her to ends that the manipulated person does not perceive as justified, or simply does not agree with (Norrick, 2009). This kind of manipulative anticipation oversteps the boundaries of other people’s “territories of information” (Kamio, 1994), or impinges on the private spheres of the very people whose sufferings we empathize with (Heritage, 2007). An emancipatory pragmatics with a proactive, anticipatory thrust should be aware of these dangers, and not fall back in the old groove of paternalistic colonialism, by which the “poor natives” were considered as unruly children, to be educated in accordance with the beliefs of the colonizers and “formed” in their images.

Societal pragmatics, while being aware of this danger, nevertheless should stride boldly ahead. Ultimately, even less preferable actions are better than taking no action at all. But our actions should be informed by correct, theoretical insights, and this is where societal pragmatics, in its proactive, anticipatory version, comes in. Earlier, I said that pragmatic linguistics has as its aim the unveiling of abuses of language; societal pragmatics, in force of its emancipatory potential, will have to anticipate such abuses of language and prevent manipulative discourses from being acknowledged as the only correct way of talking about our actual problems, be they of a political, social, or even ecological nature. Thus, societal

pragmatics embodies the practice of a socially motivated and socially responsible societal discourse.

Sociocognitive Approaches to Second Language Acquisition

DWIGHT ATKINSON

Historically, it has been assumed that second language acquisition (SLA) is a mental process, which takes place largely in isolated cognitive space (e.g., Long, 1997). But what if SLA extends freely into body and world? What would it look like then? These are the questions motivating sociocognitive approaches to SLA.

Theoretical Foundations

The main conceptual foundations of sociocognitive approaches are: (a) ecological perspectives on mind and activity, (b) extended and embodied approaches to cognition, (c) situated studies of multimodal interaction, and (d) research on “intention-reading” and behavioral synchrony.

Ecological Perspectives on Mind and Activity

From Descartes onward, the separation of mind from body and world has dominated Western thought. Only recently (with a few major exceptions) have concerted challenges arisen. Ecological approaches emphasize relationality over discrete elements: In ecosocial systems, mind, body, and world are co-dependent for their functionality and existence.

Bateson (1972), a major proponent of ecological approaches to mind, described an axe-wielder felling a tree: “Each stroke of the axe is modified or corrected, according to the shape of the cut face of the tree left by the previous stroke. This self-corrective . . . process is brought about by a total system, tree–eyes–brain–muscles–axestroke–tree” (p. 317). The quotation-ending list suggests the activity’s integrated nature: Environment, body, cognition, and tool-wielding cannot be separated. Bateson concluded: “The mental characteristics of the system are immanent, not in some part, but in the system as a whole” (p. 316).

Extended and Embodied Cognition

Extended and embodied approaches to cognition are currently sweeping cognitive science, but have barely affected SLA studies. Both approaches assume that human intelligence is ecologically adaptive—that it functions to aid survival in an ever-changing environment. Classic cognitive science, on the other hand, views cognition as the computational crunching of decontextualized, logic-like problems and data (Boden, 2006).

The case for cognition-as-adaptive-intelligence goes as follows: Intelligence originally evolved to promote survival-enhancing behavior—obtaining food and shelter, mating, child care, and so forth. Even today, humans are considerably better at solving real-world problems than the abstract puzzles of cognitive tests and school mathematics (Glenberg, 1997). This is not to dismiss “offline” cognition, but it does relocate its ultimate basis in moment-to-moment adaptivity. Thus, means–ends reasoning probably arose in the context of procuring food and building within-group alliances (Dunbar, 1996), and is still used largely for practical purposes.

Following Bateson, *extended* theories of cognition argue that, far from being buried in minds, cognition projects out into the world. Thus, clocks, organizers, and calendars participate intimately in cognitive planning and execution; cognition-for-environmental navigation depends heavily on environmental structures, for example, road grids, signs, traffic lights, lane markers, GPS signals, maps, other cars, radio information, and so forth, when driving. Even academic writing is an intricate dance of onboard cognition with books, notes, computers, revision processes, and, sometimes, writing groups, conferences, and interlocutors (Clark, 2001). Although such phenomena are standardly treated as distinct from cognition, consider this alternative:

If, as we confront some task, a part of the world functions as a process which, *were it done in the head*, we would have no hesitation in recognizing as part of the cognitive process, then that part of the world *is* . . . part of the cognitive process. (Wilson & Clark, 2009, p. 8)

This view's implications are radical: Cognition extends promiscuously into the world, at least in certain cases. Regarding SLA, the corresponding argument is that we learn in integrated *sociocognitive* space (see below).

Embodied approaches to cognition study the body's role in cognitive processes. Classic cognitive science views mind as separate from body, yet research shows that: (a) perception, cognition, and sensorimotor action share common neural underpinnings; (b) cognitive representations are body-based; (c) cognitive development depends on embodied experience; and (d) cognition likely evolved to keep the body environmentally viable (see Glenberg, 1997; Gibbs, 2005; Atkinson, 2010a for reviews).

Situated Studies of Multimodal Interaction

Most language processing and learning research assumes environments reduced to cognition and language. Yet gestures, smiles, body orientations, and paragraph breaks are just as expressive as lexis, intonation, and grammar. In fact, many such sign systems function integratively.

Anthropologists led by Goodwin (e.g., 2006) have unveiled the multimodality of meaning-making in interaction. Real-world communication results from diverse, juxtaposed sign systems, for example, in face-to-face interaction: body orientation, gesture, gaze, facial expression, intonation, grammar, lexis, and in-the-world meaning-making resources like graphic artifacts (e.g., charts, datebooks), tools (e.g., computers, blackboards), and structures (e.g., road grids, classrooms). If meaning is made via such ecologies, then SLA must also depend on them. Obviously, this is far from seeing SLA as the product of isolated minds.

Intention-Reading and Behavioral Synchrony

Humans are master intention-readers—our sociality depends on our sensitivity to others, and corresponding behavioral adjustments. Levinson (2006a) located this sensitivity in our “interaction engine”—our evolved capacity to: (a) ascribe intentions to others, (b) know what others are thinking about our thinking, (c) have “Gricean intentions”—“intentions driving behaviors whose sole function is to have the . . . intentions recognized” (Levinson, 2006b, p. 87), and (d) deploy interaction-promoting behaviors like greeting, turn taking, and repair.

Levinson highlights the cognitive side of reading intentions, which furthermore seem to be largely discrete and conscious. Research on *embodied intention* (Yu, Ballard, & Aslin, 2005) suggests that gaze, gesture, body orientation, and so forth, also contribute crucially

to understanding a broader range of phenomena, from discrete intentions to inchoate emotions. As discussed below, this has major implications for SLA.

The ability to “read” others fluently and easily enables the exquisite behavioral synchrony underlying adaptive human interaction. Such coordination promotes—just as disalignment retards—efficient, effective social action. Witness the feeling of being so highly aligned with an interlocutor that she really does seem to read one’s mind, versus the fact that conversations featuring excessive pausing, false starts, and repair tend to be regarded as *failed* conversations.

Sociocognitive Approaches to SLA: Three Principles

Three principles underlie sociocognitive approaches to learning/SLA: (a) the *Inseparability Principle*, (b) the *Learning-is-Adaptive Principle*, and (c) the *Alignment Principle* (Atkinson, 2010a).

The Inseparability Principle

This principle states that mind, body, and world collude in producing SLA-as-ecosocial action. Consider Bateson’s woodcutting scenario again, this time vis-à-vis learning. Each time mind-body-axe strikes tree, a new ecology emerges: as the tree is reconfigured, the whole system adapts. At a first approximation, learning just *is* this process whereby mind-body-world is restructured through ecosocial action (Atkinson, Churchill, Nishino, & Okada, 2007).

Learning/SLA thus involves the rearrangement of organism-plus-environment. This differs radically from the mainstream perspective, wherein linguistic input is extracted from the world and processed by “lonely” cognition. Sociocognitive approaches emphasize the *thickening* of mind-body-world relations over their progressive detachment and attenuation: instead of building elaborate, self-contained cognitive world models, we learn to better use “the world [as] its own best model” (Brooks, 1990, p. 5).

This is not to suggest that nothing is internalized in SLA, but fully elaborated and enclosed cognitive-linguistic representations are implausible due to their non-adaptivity: Human behavior must be environmentally open and situationally responsive to ensure worldly survival. Alternative understandings of language emanate from its everyday uses: Phatic communion is thought to consume most of our linguistic efforts (Dunbar, 1996), and primarily involves using linguistic/semiotic tools to align with others. Grammar, from this perspective, is substantially for social interaction (Ochs, Schegloff, & Thompson, 1996).

The Learning-Is-Adaptive Principle

Assuming that cognition is adaptive intelligence, this principle foregrounds the role of learning in ecosocial adaptivity. What else could learning be than the process by which we more effectively align with our environments? As mentioned above, viewing SLA as the progressive extraction of language from world is *prima facie* implausible if language is for social interaction.

Bateson’s example highlights learning-as-adaptivity. We learn by doing—through effecting ecosocial action. Our actions create new situations, inducing new *actions* in ourselves and others. Thus, in trying to use a new language, we produce social action, which reconfigures the mind-body-world we share, or are trying to share, with others. This is a far cry from theories which sever acquisition from use and competence from performance.

The Alignment Principle

This principle holds that SLA occurs via alignment—the complex, often public means by which humans effect ecosocially adaptive interaction (Atkinson et al., 2007). Alignment undergirds sociality:

A social relationship may be said to exist when . . . people reciprocally adjust their behavior to each other with respect to the meaning . . . they give . . . it, and when this reciprocal adjustment determines the form . . . it takes. (Weber, 1922/1978, p. 30)

Reprising Bateson's example one last time, imagine the tree felling now as a *two*-person operation—two individuals alternately striking a tree. This interaction is “triadic”—the axe-wielders affect each other while affecting the world, adjusting their responses to the ever-changing environment. How do they do it? Crucially, they monitor each other's actions, including their embodied intentions and emotions. Thus, if one member—let's call him Toshi—reorients his gaze, facial expression, and body markedly as his turn to strike comes, a new meaning—a new activity—is potentially signaled: Maybe Toshi wants to rest. His partner—call her Deborah—will adjust her actions accordingly. (Note, however, that although conventional expectations guide social behavior, they by no means determine it.) This in turn affects Toshi—depending (partly) on the nature of Deborah's actions, he may proceed to rest or resume chopping.

The Alignment Principle holds that embodied intentions and emotions, in concert with worldly structures like dictionaries, bars, classrooms, and grammar exercises, lead SLA: ecosocial alignment—the outcome of evolutionarily deep capabilities including Levinson's interaction engine, Yu et al.'s (2005) embodied intention, and Wilson and Clark's extended cognition—supports SLA at every turn. It does so by promoting attunement across social actors-plus-environment. That is, communicative action occurs across a broad array of semiotic resources, many of which precede language and are substantially universal. Far from being locked in individual minds, these resources are “in the light”—circulating openly in the sociocognitive environment. If they were not publicly present—if *all* language learning were not built on a base of perceivable, understandable, and actionable communicative resources—then how could it occur? In that case, universal grammar would be the only plausible explanation.

Interaction furthermore takes place in *situated activity systems* (Hutchins, 1995)—commonly occurring, more-or-less structured ecologies in which human beings, social practices, semiotic tools, and non-human environments come together to perform social action. Consider service encounters. Although locally instantiated, service encounters share a common structure the world over: sellers offer buyers goods; buyers determine which goods they want, then request them from sellers; sellers give goods in exchange for money or other goods. This general schema provides a *participation framework*—an arrangement of roles and activities which are highly predictable and thus easy to align with, even when participants have little else in common. Substantially all human activities occur within activity systems—systems which provide general frameworks for understanding. In so doing, they constitute “alignment machines”—frameworks in which collaborative action can be performed, including in the absence of a common language. Activity systems thus powerfully scaffold SLA.

Sociocognitive Approaches to SLA: Examples

In this section I review three studies suggesting the importance of alignment in SLA.

Embodied Intention in SLA

In exploratory research, Yu et al. (2005) examined the effects of gaze on the acquisition of L2 word segmentation and vocabulary. An L1 Mandarin speaker wore a tiny head-mounted video camera that filmed the (wordless) picture book he held as he narrated a story based on its pictures. A second camera recorded the speaker's eye movement vis-à-vis the pictures as he narrated. The latter video results were then superimposed on the original video by indicating gaze direction with crosshairs.

Twenty-seven monolingual English-speaking participants were divided into three equal groups, which respectively (a) watched the combined video (including audio), that is, featuring the "intention-cueing" crosshairs; (b) watched the original video (including audio), that is, without crosshairs; or (c) listened to the audio track only. A multiple-choice test of speech segmentation and vocabulary was then administered to all participants. Results showed statistically significant advantages for the video-plus-crosshairs group in both speech segmentation and vocabulary acquisition.

This research suggests how alignment can facilitate SLA. The crosshairs more closely approximated a pointing finger than gaze, even if the latter is attended to closely (as Yu et al.'s literature review substantiates, at least for L1 learners). The results nonetheless indicated how ecosocial environments can provide cues for SLA. As shown below, multimodal alignment is pervasive in SLA contexts, providing many "ways-in" to naturalistic SLA.

Gaze in Conversation

Goodwin (1980) studied the role of gaze in conversational organization. In initiating speech, speakers bid for listeners' attention. This attention is usually signaled by the listener gazing at the speaker. The speaker typically confirms the listener's gaze by gaze-checking early in the utterance. If she finds the listener gazing in return, she continues speaking; otherwise, she typically pauses until the gaze arrives, or restarts and repairs the utterance. The latter is shown in (1), where "LG" marks onset of listener gaze (Atkinson, 2010b, following Goodwin, 1980, p. 275 and 2006, p. 101):

- (1) A: We went t- I went to bed really early last night
 B: LG _____

Goodwin (2006) described the opportunities these phenomena provide for language learning. First, pausing segments the speech stream, thereby providing valuable information regarding what constitutes units in the language. Second, restarts make public the constituent structure of utterances, for example, the base predicate in (1). Third, restarts present options for paradigmatic substitution, for example, *we* versus *I* in (1). Conversation thus provides language-learning opportunities via natural processes of alignment and interaction.

Alignment in Grammar Exercise Completion

Atkinson et al. (2007) studied alignment in a videotaped English as a foreign language (EFL) tutoring session. "Tomo," an experienced EFL teacher, was working with "Ako," a Japanese junior high school student, on a school-assigned grammar exercise.

In (2), from Atkinson et al. (2007, p. 175), Ako and Tomo translate part of the Japanese prompt, *Anata wa ima made ni tegami o kaita koto ga arimasuka?* ('Have you ever written a letter in English?'):

- (2) 01 A: ((Reads first part of exercise item quickly under her breath))
 > °Anata wa ima made ni eigo de tegami °< (2.0) Ima made ni=
 [*Lit: You [SUBJ] ever in English letter*] *Ever*
- 02 T: ((Softly shadows A's volume, intonation, and bodily orientation))
 =°Un ima made°
 Right, ever
- 03 (1.0)
- 04 A: [Ne:ba:
 Never
- 05 T: [>Sakki no tsukaeba iin janai?< ((Searches unsuccessfully for
 earlier item on worksheet, using pen as pointer))
 Why not use the one you used before?
- 06 A: Ima made (.8) ne- e:va ka
 Ever. Ne- ever?
- 07 T: Have you ever toka nantoka=
 Have you ever blank
- 08 A: =Have you e:va writu, written=
 Have you ever write, written
- 09 T: =Un.
 Right.

In line 1, Ako aligns with the first part of the prompt by reading it quickly under her breath. She then repeats—thus further focusing attention—the time adverbial *ima made ni* ('ever'), a crucial indicator of verb tense. In line 2, Tomo aligns with Ako in at least six ways, by (a) timing her own utterance to follow Ako's without a pause, (b) using an agreement marker (*Un*, 'Yes'), (c) speaking in the same quiet tones as Ako, (d) partially repeating the adverbial, (e) using the same 1–3–2 intonation pattern used by Ako in repeating the adverb, and (f) assuming a bodily orientation which is almost identical to Ako's (see Atkinson et al., 2007, Picture 1.1). Next, in line 4, Ako takes a first stab at translating the adverbial, offering the inaccurate *ne:ba*: ('never').

Tomo's response (line 5) is an attempt at extended cognition. She suggests using an already completed exercise item containing the target structure as an in-the-world model. On searching, however, Tomo fails to locate the item. Ako then reverts to guessing the adverbial's translation, attaining the correct answer in three steps: (a) restating the Japanese adverbial in the form Tomo earlier used, (b) partially repeating her earlier guess with *ne-*, and (c) producing the correct answer (*e:va* 'ever').

In line 7, Tomo takes Ako's *e:va* and repackages it in a grammatical construction, thus reconfiguring the mind-body-world system substantially. More specifically, Tomo builds Ako's *e:va* into a fill-in-the-blank frame, *Have you ever toka nantoka* ('Have you ever blank'), thereby reformulating the task as a search for the correct form of the main verb. In so doing, Tomo narrows the sociocognitive "problem space" considerably, providing Ako with significant in-the-world scaffolding. Ako's response confirms Tomo's decision: Ako immediately repeats the grammatical frame, filling the blank first with *writu* ('write'), and then self-correcting to the target form, *written*.

This example indicates how alignment may function in SLA. Most notable is the public nature of problem solving—while minds are clearly involved, so are bodies and world: the three work together. Thus, in line 1, Ako "externalizes" her cognition by reading the exercise item aloud, and then does the same with the adverbial. In so doing she publicly signals her attentional focus, thus allowing Tomo to align and co-cognize with her. Likewise, in lines 6 and 8, Ako makes incorrect guesses before hitting on the correct answer, as if by linguistically materializing the former she paves the way for the latter. For Tomo's part, she multimodally aligns with Ako in line 2, thereby confirming and co-constructing Ako's focus on the adverbial; she suggests an extended cognitive solution to translating the

adverbial in line 5; and in line 6 she radically reconfigures the task by building a fill-in-the-blank scaffold around Ako's correct translation of the adverbial. Through all these activities, alignment operates in a case of potential SLA.

Conclusion

Historically, SLA has been viewed largely as the cognitive intake and processing of linguistic input. While not denying that internalizing and processing input are important—albeit input more widely and multimodally construed—sociocognitive approaches highlight a different sense of the input metaphor: how learners *themselves* are input into rich socio-cognitive environments—environments supporting L2 development at every turn (Atkinson, 2002). If SLA extends across mind, body, and world, and if human sociality is conducted via situated activity systems, then it will be impossible to view mind as the *sanctum sanctorum* of SLA.

Sociocultural Theory

JAMES P. LANTOLF AND MATTHEW E. POEHNER

Vygotsky's (1926/2004) monograph *The Historical Meaning of the Crisis in Psychology* is his foundational work in which he lays out the theoretical basis of his theory of culturally mediated mind, which is eventually expanded into his much better known publication *Thinking and Speech* (Vygotsky, 1987). In *The Crisis* Vygotsky proposes his solution to the classic Cartesian mind/body problem which had fractured psychology, and in many ways continues to fracture Western psychology to the present. In Vygotsky's day, one set of psychological models (e.g., Freudian psychology, Gestalt psychology, hermeneutic psychology) attempted to access mental processes through introspection externalized through speech, while the other (e.g., American behaviorism, Pavlovian reflexology) focused on movement of the physical body as an external manifestation of unobservable mental processes. Those trying to bridge the gap between the two adopted an eclectic approach whereby they attempted to weld elements from each psychology into a unified theory of mind. Needless to say, these efforts failed to generate workable hypotheses and methods for psychological investigations. Wilhelm Wundt, considered by most to be the founder of modern experimental psychology, proposed a complete separation between psychologies that focused on higher-order mental processes (i.e., voluntary memory, perception, attention, language, and rational thinking), which he understood to originate with *culture*, and those that dealt with more basic, *biologically governed*, non-voluntary processes including reflexes and non-voluntary memory, attention, and perception that humans shared with other higher mammals. Wundt recommended that voluntary processes be assigned to disciplines other than psychology, including anthropology (in his time, sociology), linguistics, and literary studies and that the involuntary, biologically endowed processes remain in psychology to be studied through experimental (scientific) methods, privileging measurement of discrete traits and behaviors, as in reaction-time research (for a fuller account of Wundt's argument, see Cole, 1996). Wundt's solution then reinforced Cartesian mind/body dualism, widening rather than narrowing the gap between the different approaches to the study of mind. Vygotsky argued for a third option, which was to create a completely new psychology based on Marx's materialist dialectic.

Vygotsky's Dialectical Scientific Psychology

Dialectics offers a way of overcoming the oppositions at the core of dualisms not by choosing one option over the other, but by showing how they can be brought together into a unified synthesis in which both components are necessary for the system to function. A compelling example is provided by Marx (1858/1972) in the *Grundrisse* (the precursor to *Das Kapital*), where he discusses the dialectical relationship between production and consumption. Accordingly, the production of goods is stimulated by the needs of those who consume the goods while at the same time the very production of goods awakens the need for consumption. Without production there can be no consumption and without consumption production is useless. To paraphrase Marx (1858/1972, p. 225), a house not lived in is not a house and a dress not worn is not a dress. A dialectical relationship, then, is comprised of a unity formed by two objects or processes that seem to be, for all intents

DOI: 10.1002/9781405198431.wbeal1084

and purposes, contraries or opposites. Each component can still be identified independently of the other, but without the other the full force of the unity is compromised or lost completely. Consider for a moment a simple object, such as a pencil with an eraser on one end and a sharpened point on the other. One end of the pencil creates symbols and representations, while the other erases them, the human agent functioning with this tool to compose and erase. It's only in this creative activity that the dialectical relation is established. Both processes are independent and can function without the other, but together they enable the creation of written texts—a process that usually requires creation and elimination of visible marks representing our thinking activity.

Vygotsky brought the dialectic into psychology and argued that human consciousness, the proper object of study for psychology, results from the dialectical unity of two distinct though necessary components: our biological endowment and our cultural inheritance. Without both of these a human psyche was impossible. Biology endows us with the necessary foundation, a brain, but a brain is not a mind. For this we need culture, which endows us with the capacity to intentionally organize and control (i.e., mediate) those processes that come ready-made with a brain. The synthesis of these components results in uniquely human mental life.

If human thinking were fully determined by the brain, then the relationship between humans and the world would be as direct as it is with other forms of life. This relationship would largely be characterized as stimulus and response. The organism would react and adapt to circumstances in its environment, as happens in the case of other animals. Human consciousness is unique in that culture, including artifacts (e.g., language, numbers, art, music, etc.) and activities (e.g., play, work, leisure, worship, politics, economic systems, etc.), is inserted between the human organism and the world and thus creates an indirect, or *mediated*, relationship. Vygotsky reasoned that just as humans can change and control the world through the use of physical tools—culturally created artifacts that come between humans and the world—we can also change and control our mental life through the use of culturally created symbolic tools, the most important of which is language. Hence, humans do not merely react and adapt to the world; they act on and change the world. In the same way, they act on and control their mental life.

A culturally created artifact such as language endows humans with the ability to filter and organize in specific ways various aspects of the physical world and it further endows us with the capacity to inhibit reactions to incoming stimuli, a necessary feature of planning. In turn, planning allows us to carry out activities symbolically, on the ideal level, before we implement them in the material world. Thus, architects build houses on paper, or computers, symbolically before building them in reality. This allows the architect to detect and avoid potential problems before they occur in three-dimensional space. In addition, the plans can be transmitted to other individuals, who following the plans are able to construct the edifice. The dialectic between symbolic (ideal planning) activity and concrete physical (objective) activity imbues humans with the capacity to intentionally and systematically change the world and with it themselves.

Genetic Method: Vygotsky's Historical Developmental Approach to Mind

Having formulated a dialectical basis for psychology, Vygotsky realized that traditional procedures (i.e., reaction-time experiments, introspection) for studying mind were incommensurate with an understanding of humans as historical beings. He recognized that the coming together of biology and culture was itself a historical process. That is, humans were not born as fully thinking beings; rather they became such as they were socialized

into their cultural communities. To study human thinking could not be adequately achieved once a human psyche had been fully formed and was operating smoothly, as is the case with normal adults. Instead, following Marx, Vygotsky proposed a methodology which traced the historical development of human consciousness. The methodology is known as the *genetic method*, because it is predicated on the notion that mind develops as individuals (and even entire communities) appropriate and use mediating artifacts found in a culture to organize and regulate their thinking.

The most significant artifact humans use to regulate their thinking is language. As a symbolic system language has a reflexive capacity whereby it is directed outward at others during social interaction and inward at the self during mental activity. The aspect of language that matters here is not linguistic form but linguistic meaning. Accordingly, higher (i.e., voluntary) forms of human mental activity are semiotically mediated. To understand how the process of mediation functions requires observation of the processes as they are being formed during the *ontogenesis* of individuals or the *cultural history* of an entire community. When children start to appropriate language they begin the process of gaining control over their own thinking. When communities appropriate new symbolic-making capacities, as for example occurred during the computer revolution, they learn new ways of mediating their relationship to the world and to each other.

One of the most important capacities that human adults possess, and which children must develop, is planning. As explained, a core feature of this process is planning on the ideal plane through the use of language (and other symbolic systems) before acting on the concrete plane (see the architect example above). The advantage of being able to plan symbolically is immeasurable. Early in life children act without rational thinking (i.e., without planning), but following years of interaction with representatives of their culture, whose primary responsibility is to socialize them into the community, they develop the capacity to act as a consequence of rational thought, which means they act in accordance with plans formulated primarily through the semiotic capacity offered by language.

Luria (1982), an influential colleague of Vygotsky's, documented the historical phases through which children develop the capacity to plan actions through language. At first they are unable to plan and merely react to stimuli from the world. Next they are regulated by the sounds but not the meanings imparted through language. Then they are regulated by the meanings of language expressed in the social speech of others. They develop the ability to use language, as in private speech, to regulate their own behavior but the speech must be external (i.e., social in form but psychological in function). Finally, they use language internally to regulate their mental, and even physical, behavior. When this stage of development is reached, a new dialectical unity is created which brings together the ideal symbolic form of activity (i.e., planning) and the concrete material form of the same activity in the physical world. Thus, for example, children at this stage, as with adults, are able to plan a drawing before materializing it with paper and pencil. Earlier in their development children can state what they have drawn only after creating the image.

Theory and Practice in Dialectical Science

Intentionally planning objective action on the symbolic, or ideal, plane is connected to the central dialectic of the theory that emerges from Vygotsky's integration of Marx's (1845/1978) "11th thesis on Feuerbach". The 11th thesis can be paraphrased as follows: the function of theory is not to interpret the world but to change it. In adherence with this principle, Vygotsky argued that the true test of a theory is not the quality of the ideas it generates or the extent to which it holds up in a laboratory but the extent to which it results in changing practice and, with it, the ways in which humans live and develop. In *The Crisis*

Vygotsky (1926/2004) compares the relationship between theory and practice in dualistic psychology and in the new dialectical psychology he proposed. In the former practice depends on theory, but the reverse is most definitely not the case. Practice is the “conclusion, the application, an excursion beyond the boundaries of science, an operation which lay outside science and came after science” and most of all success or failure of the application has “practically no effect on the fate of the theory” (p. 304). In dualistic science, as Vygotsky argued (p. 304), theory does not depend on practice and therefore it need not have any real-world consequences.

Following through on the implications of the eleventh thesis, Vygotsky insisted that for the new dialectically grounded psychology, practice is the site *sine qua non* for testing theory. It “pervades the deepest foundations of the scientific operation and reforms it from beginning to end. Practice sets the tasks and serves as the supreme judge of theory, as its truth criterion.” Moreover, practice “dictates how to construct the concepts and how to formulate the laws” (p. 304). To link this back to earlier comments with regard to planning and activity, we can see that theory represents the ideal (i.e., the plan), symbolically formulated component of activity, while practice is the concrete instantiation of the ideal. Hence, activity is carried out on two planes, the ideal and the concrete, but each is not independent of the other. Each ineluctably depends on the other. Without a plan or a theory activity verges on mindless behavior, and without practice an ideal plan or theory is useless verbalism. It is like the dress not worn or the house not lived in.

The unity of theory and practice argued for by Vygotsky is known as *praxis*, a concept that has a long and complex history traceable to Greek philosophy (see Bernstein, 1971; Sanchez Vasquez, 1977). As Sanchez Vasquez (1977, p. 149) puts it, “All praxis is activity, but not all activity is praxis,” because “human activity properly speaking only occurs when actions designed to transform an object are initiated on the basis of an ideal result or end, and culminate in an actual, concrete result or product” (p. 150). Without a guiding idea or theory, activity lacks an objective goal and therefore is not praxis. For instance, when humans walk along a beach they leave footprints in the sand. The making of footprints, unless done with a plan, as for example to leave a trail for someone else to follow, is not praxis although it qualifies as activity. The key to praxis is the unity and bidirectional flow of ideal (i.e., theoretical) activity carried out symbolically and concrete activity carried out in the material world.

Sociocultural theory is a theory that is fundamentally and necessarily connected to the world as the site where the theory is to be tested. For the past nearly 80 years it has been tested in a wide array of venues, including the workplace (see Engeström & Middleton, 1996), hospitals and clinics (Luria, 1973, 1979; Vygotsky, 1993), social reform (Ratner, 2006), and above all education (see Ilyenkov, 1974; Newman, Griffin & Cole, 1989; Moll, 1990; Newman & Holzman, 1993; Kozulin, 1998; Daniels, 2001; Wells & Claxton, 2001; Stetsenko & Arieviditch, 2004; Karpov, 2005; Holzman, 2009). As becomes apparent from reading this research, changing things through praxis is at the same time understanding the very object(s) of study that changes. In other words, to change is to understand and to understand means to change (not merely to observe). From this perspective, the previous separation between basic and applied research evaporates. As Vygotsky (1926/2004, p. 305) argued, “applied psychology is psychology”—a scientific discipline that both generates (rather than consumes) theories and gauges the validity of its theories through practical real world activity.

Sociocultural Theory and Interlanguage Pragmatics

EMILY F. RINE AND RÉMI A. VAN COMPERNOLLE

Introduction

Vygotskian sociocultural theory (SCT) (e.g., Vygotsky, 1978, 1986; for second language [L2] development, see Lantolf & Thorne, 2006) has been extended to interlanguage pragmatics (ILP) research in a number of interesting and fruitful directions since the 1990s. The central concept of SCT, *mediation*, refers to the idea that higher forms of human mental activity (e.g., intentional memory, voluntary attention, communication) involve the integration of culturally constructed auxiliary stimuli, commonly called *mediational means* or *artifacts*, foremost among which is *language*. Internalization of mediational means enables humans to control basic (i.e., biologically endowed) psychological functions from the outside (Vygotsky, 1978), transforming them into specifically human, culturally based mental abilities. Within this perspective, ILP development is seen as a socially mediated (i.e., culturally based) process rather than an acquisitional (i.e., internal, inside the “mind/brain” of the learner) phenomenon. In addition, from the perspective of SCT, ILP development is as much about consciousness as it is about performance abilities.

The concept of mediation has been invoked in two distinct ways within SCT-informed ILP research. The most common invocation of the term refers to assistance provided by a more competent person, such as teacher or peer assistance during a learning task or communicative event. This type of social, or *interpersonal*, mediation supports learners in developing their understanding of or ability to use pragmatic features of language. A less frequently discussed conceptualization of mediation—at least in ILP research—relates to Vygotsky’s argument that language is itself a mediating artifact. Pragmatic features of language mediate social actions, identities, and the qualities of interpersonal relationships. The question for ILP researchers centers on the extent to which L2 pragmatic features come to be personally meaningful mediating artifacts for learners. To be sure, the two emphases are interrelated, with the former focusing on the processes by which the latter may develop. In the general SCT literature, a similar distinction has been made between *meta-mediation* (i.e., human mediation provided to facilitate the internalization process) and *psychological mediators* (i.e., the mediational means to be internalized; see Negueruela, 2008).

The interplay between social mediation and the internalization of mediational means may be described in terms of what is probably the best-known concept in SCT: *zone of proximal development* (ZPD; Vygotsky, 1978). The ZPD is the metaphorical space between what the learner is able to do independently (i.e., completed development), on the one hand, and what the learner is able to do with support from another person, on the other. In the ZPD, mediating agents (e.g., teachers, more expert peers) support the learner in internalizing mediational means; hence the connection between meta-mediation and psychological mediators, as described above. Importantly, the ZPD concept is not co-equivalent with related notions of assisted performance, collaboration, scaffolding, and so forth, which primarily focus on the concept of “assistance” during performance; rather, the ZPD fundamentally entails a transformative process in which mediational means are

internalized, via meta-mediation, as personally significant artifacts for the learner (Lantolf & Thorne, 2006). As noted above, the internalization of pragmatic features of language is not coterminous with gains in performance abilities, but rather describes the extent to which learners are able to (re)mediate their interactions with the world through the L2, including the accomplishment of social actions, the performance of social identities, the creation and maintenance of particular qualities of social relationships, and so forth.

The remainder of this entry discusses two strands of SCT-informed ILP research carried out to date. First, we report the findings of observational research using SCT as a theoretical or analytic lens as a means of interpreting questions related to ILP development. While these studies focus primarily on issues of interaction, participation, and access to L2 communities, they also illustrate the advantages of using an SCT to observe ILP development. Second, we address a relatively new wave of educational praxis-oriented SCT research into ILP development. Such research incorporates SCT principles into the design of ILP instructional programs.

Interaction, Participation, and Access in ILP Development

As noted above, a central claim in SCT is that a person's cultural development is mediated by more expert or competent members of society. Social mediation takes place as children or other learners (e.g., adults in a classroom), in cooperation with others, take part in culturally organized activities in which the appropriate mediational means may be modeled, explained, or both. For this reason, SCT-informed ILP research accounts for the role of interaction and participation in, as well as access to, developmentally beneficial forms of activity. It is also important to note that SCT research into ILP does not focus solely on predetermined sets of pragmatic features (e.g., speech acts) but, additionally, considers patterns of interaction and participation in general to be pragmatic resources for the accomplishment of social actions, both within and beyond formal, structured educational environments.

In one of the earliest studies to invoke Vygotskian concepts in the field of ILP, Shea (1994) challenged the Gumperzian analytical tradition of interpreting miscommunication in intercultural communication as a "mismatched interpretation of contextualization cues" due to differences in cultural backgrounds and styles (p. 516). Shea observed the interactions between advanced Japanese English as a second language (ESL) speakers and their native speaker (NS) English interlocutors in order to show how the *quality* of the interlocutors' responses to the non-native speakers (NNSs), rather than cultural differences, directly affected the NNSs' opportunities for learning and participation in the interactions. Shea illustrated that the ways in which utterances are interpreted in interaction are mediated by how interlocutors position themselves and are positioned along several dimensions in conversation.

Although Shea's (1994) study provided an important message about the role of access to participation in a given practice for development in contexts outside of the classroom, more common to ILP research are those studies involving and interested in classroom interactions. In two studies involving a Spanish as a second language classroom, Hall (1995, 1998) showed how differences in the ways the initiation-response-feedback (IRF) sequence unfolded during a particular practice called "practicing speaking" over the course of one semester had both interactional and social consequences for the members of one particular class. In Hall (1995), the author was interested in how topics were established and discursively managed in an interactive practice designed to provide speaking opportunities in Spanish. She found that the devices used to create topics and maintain topical coherence were very limited and different from the types of linguistic devices used in naturally occurring conversation; thus, "the developmental consequences of providing

such a limited repertoire of possibilities for students in any classroom are likely to be as limited" (Hall, 1995, p. 53).

In a follow-up study, Hall (1998) provided a different analysis of the same classroom, focusing this time on the effects the structure of the IRF sequence itself had on opportunities for participation in the class. Hall discovered that while the structure of the IRF sequence itself remained fundamentally the same for each of the participants, the ways in which the teacher responded to and allocated turns based on the follow-up move (i.e., granting two students "primary" status versus the "secondary" status of the other two) directly impacted the differential quality and quantity of learning opportunities afforded to each of the students. The importance of how the teacher allocated and responded to student turns for creating opportunities for learning was similarly noted by Antón (1999) in a study of two first-year university French and Italian classes. By shifting the discourse moves they use from "teacher-centered" to "learner-centered," teachers involve the students in negotiation, which functions to scaffold the students and provide them with assistance in the ZPD (p. 303).

While the dynamics between teachers and students are certainly an important part of any classroom experience, several researchers showed that peer-to-peer interaction is often-times just as powerful for inciting development, allowing participants to act as *both* expert and novice in the same task, such as in collaborative group work or in one-on-one interaction. In a Japanese as a foreign language classroom, Ohta (2001) found that opportunities for development may still be found within the IRF sequence if we shift our expectation of what the target of learning is when using this type of sequence. More specifically, teacher-directed IRF sequences may be massively restrictive in who may speak at a given time (i.e., the teacher overwhelmingly produces the assessment tokens); however, students are, by the same token, exposed to abundant examples of listening assessments being done by the teacher on a daily basis. This input, coupled with peer-to-peer practice doing the IRF sequence, allowed students to develop the pragmatic resources for being an active listener by improving use of response tokens and assessments over time.

A series of studies by Belz and Kinginger investigating development in telecollaboration and study abroad (Belz & Kinginger, 2002, 2003; Kinginger & Belz, 2005) have expanded this line of research by arguing that SCT "suggests a principled way toward documentation and explanation of the specific manner in which intercultural interaction fosters language development in particular contexts" (Kinger & Belz, 2005, p. 370). In particular, they have highlighted the advantages of performing *microgenetic* (moment-to-moment) as well as *ontogenetic* analyses on data to illustrate development within the paradigm of French and German second person address (i.e., French *tu* vs. *vous* and German *du* vs. *Sie*). The concept of microgenesis comes from Vygotsky's (1978) developmental (or "genetic") approach to cognition. According to Vygotsky, the only way that one can understand development is to situate it in terms of its historical origins in the material, social world and to trace the physical and social transformations it undergoes. Comparing the two types of analysis, Kinginger and Belz (2005) note that "Microgenetic study of *language* development closely examines the particular features of interactive settings as development takes place, whereas ontogenetic study is more longitudinal in scope, tracing changes as they occur over more extended periods of time" (p. 373, italics in original). In addition to showing how a telecollaborative partnership afforded a wider range of opportunities for using the T form (*du*) in sociopragmatically appropriate ways, Belz and Kinginger (2003) were able to show how, through a combination of explicit peer instruction, opportunities to observe peer language use, and the motivation to maintain positive face with their German peers, most of the American students were able to either dramatically or gradually improve the appropriateness of address form use in German over the span of the telecollaborative partnership.

In Kinginger and Belz (2005), the authors presented two case studies, one from a German–American telecollaborative partnership and one from an American student studying abroad in France, the former highlighting a microgenetic analysis and the latter an ontogenetic one. These complementary analyses combined learners’ performance data with their metapragmatic awareness, which allowed the researchers to link environment to personal agency and identity, as reflected by their actions. Both analyses showed that developmental pathways are not linear, but idiosyncratic, and shift as the learners’ own motivations, goals, and relationships with their interlocutors change over time. In an expanded study of American university students studying abroad in France, Kinginger (2008) documented how learner histories, orientations to language, and access to L2 communities during residence abroad shaped ILP development, with specific reference to awareness and performance of address forms, speech acts (greetings and leave-taking), and colloquial vocabulary. This research is especially important because it highlighted the variability inherent in studying abroad and the qualities of learners’ achievements by focusing on the *particular qualities* of learners’ experiences in France rather than treating the study abroad experience as a monolithic, determining factor in ILP development.

Educational Praxis in ILP Development

As highlighted in the preceding section, a number of studies have used SCT as a theoretical or analytic lens for tracing ILP development. A relatively new wave of research, however, has adopted SCT principles for the design of pragmatics pedagogy—that is, rather than using SCT to interpret ILP development, SCT forms the basis for intervening through pedagogy to intentionally promote the growth of pragmatic knowledge and abilities. This, Vygotsky (1997) argued, was the ultimate goal of SCT as extended to formal educational settings—the “artificial” (i.e., intentional) development of the person.

Ohta (2005) provided an early example of extending Vygotsky’s (1978) ZPD concept to ILP instruction by reinterpreting previous non-SCT pedagogical research. She focused on the qualities of support provided to learners in a classroom context that may promote ILP development. Ohta argued that the ZPD concept may provide much-needed insight into the nature of ILP development and, at the same time, help to improve ILP instructional programs. She was not very specific in making recommendations for creating ZPDs in the classroom. Two recent research programs—reported in Vyatkina (2007; see also Belz & Vyatkina, 2008) and van Compernelle (*n.d.*)—have, however, provided more specific models of Vygotskian-inspired ILP pedagogies.

Vyatkina (2007) expanded research into ILP development in telecollaborative, intercultural partnerships by adding a pedagogical intervention component focusing on German modal particles. In other words, not only did Vyatkina trace ILP development as it occurred in a telecollaboration context, but she used the developmental learner corpus as a pedagogical tool for providing “focused instruction [on modal particles] based on corpus-enabled contrastive and developmental analyses” (Belz & Vyatkina, 2008, p. 34) throughout the two-month project. These data (i.e., the learners’ own discourse recorded as textual transcripts) were used in the classroom to focus learners’ attention on their own use of modal particles in comparison to their German native speaker interlocutors’, with guidance (i.e., mediation) from the teacher. A microgenetic analysis of the corpus revealed gains in the learners’ metapragmatic awareness of the importance of modal particle use in German conversations from the pedagogical interventions, as evidenced in their post-intervention cumulative course portfolios. Additionally, learners demonstrated a general increase in the number and variety of modal particles produced over the two-month partnership,

sometimes even superseding the number of particles produced by the German partners in a given week, although the distribution and collocation patterns of particular modal particles produced did not always match that of the NS use.

Van Compernelle (*n.d.*) adopted a concept-based approach to ILP instruction, drawing on Galperin's (1989, 1992) model of systemic-theoretical instruction, to develop a six-week sociopragmatic enrichment program for US university learners of L2 French. Concept-based instruction (CBI) focuses on teaching holistic, coherent concepts (i.e., meanings) and then mapping those concepts onto relevant linguistic forms. Concepts are presented both verbally (either in speech or in writing) and imagistically in the form of pedagogical diagrams. Verbalization tasks (e.g., explaining to oneself how the concepts work and explaining one's performance in relation to the concepts) are used to promote learners' internalization of the concepts. In turn, learners' emerging conceptual knowledge is applied to concrete communicative problems and performances, such as problem-solving worksheets and spoken-interactive tasks.

Van Compernelle's study centered on teaching the concepts of self-presentation, social distance, and power status through "concept cards" (written explanations of concepts) and a number of pedagogical diagrams depicting the concepts. The concept cards and diagrams were used to promote verbalized reflections among learners, both independently and cooperatively with an expert tutor, as a means of developing conceptual knowledge of language. The learners also engaged in a series of problem-solving and spoken-interactive tasks that were mediated by an expert teacher.

Van Compernelle demonstrated that the enrichment program simultaneously promoted concept-based pragmatic knowledge (i.e., understanding pragmatics through concepts) and enhanced performance abilities (i.e., conscious and accelerated control over language forms). However, the author stressed that developmental trajectories were not identical for all learners. Instead, because CBI serves to provide learners with coherent, systematic ways of thinking about language, it also encourages learners to construct their own personally significant (i.e., mediated) relationship between meanings and forms. With regard to ILP development in van Compernelle's study, this issue related to individuals' orientations to current and future L1 and L2 identities and desirable social relationships, and how they can be constructed through the conceptual meanings indexed by relevant language features. This inter-individual variation, van Compernelle argued, was evidence that the CBI enrichment program promoted internalization of the concepts—a process of making mediational means one's own (Lantolf & Thorne, 2006)—rather than rote memorization and non-thoughtful replication of native speaker pragmatic conventions.

Conclusion

SCT-informed research has highlighted the centrality of mediation in ILP performance and development. The bulk of this work has focused on issues of interaction, participation, and access to culturally organized activities, using SCT as a theoretical lens through which to analyze and interpret learners' actions and knowledge. More recently, however, Vygotsky's proposals have begun to inform pedagogical interventions explicitly aimed at promoting the development of ILP abilities. In addition, van Compernelle's (*n.d.*) study emphasized not only the importance of *social mediation* (in this case, interactions with an expert tutor), but also the qualities of *psychological mediators* (i.e., sociopragmatic concepts). In this sense, SCT provides the framework not only for designing pedagogies (i.e., how to teach) but, more importantly, for reconceptualizing what the object of instruction is.

Sociolinguistic Studies of Literacy

MIKE BAYNHAM

Sociolinguistics and Literacy Studies

The connection between sociolinguistics and literacy studies is not as obvious as it might seem. Introductory textbooks in sociolinguistics tend not to mention literacy in their indexes, while books on literacy do not typically list sociolinguistics in theirs. Sociolinguistics of different sorts has, however, been a significant influence in the development of literacy studies, as this entry will show. To understand how, it is important to distinguish between a number of intellectual strands or traditions within sociolinguistics.

Variationist sociolinguistics studies the correlation between linguistic variables and social factors, typically in relation to nonstandard spoken language. Although variationist sociolinguistics has made a broad contribution to literacy-related topics such as dialect and standard and language education, famously Labov's critique of Bernstein (in Labov, 1972), it has made no direct contribution to studies of literacy as such and is clearly focused on variation in spoken language.

Interactional sociolinguistics, associated foundationally with the work of John Gumperz, is concerned with the construction and interpretation of meaning in social interaction. Again, the program of work here is overwhelmingly concerned with spoken language, but the approach has been productively applied to literacy studies in Cook-Gumperz (2006).

Ethnography of communication, the third sociolinguistic strand, associated with the foundational work of Hymes, although Gumperz was also involved in its inception (see Gumperz & Hymes, 1972), is another strand which has had a major influence on literacy studies. Ethnography of communication (EoC) uses ethnographic methods to investigate and describe the communicative practices of a given speech community. From the very beginning, the EoC approach envisaged literacy, or at least written language, within its scope. Basso (1974), for example, outlines a programmatic approach to the ethnography of writing within the EoC framework. For ease of reference and to encompass other social science influences on literacy studies (introduced below), I will refer to the "social turn" in literacy studies.

The Social Turn in Literacy Studies

The emergence of the "social turn" in literacy studies can be dated to the early 1980s. While it can be characterized as sociolinguistic in orientation at least in the EoC sense, there were other significant influences from anthropology (see Street's seminal *Literacy in Theory and Practice*, 1984) and sociology (see Baker & Luke, 1991; Luke, 2004). Sociolinguistics as a discipline has shown itself to be relatively permeable to other social science influences, particularly in relation to a desire to move away from description and toward explanatory social theory of various kinds (e.g., Coupland, Sarangi, & Candlin, 2001). In this entry, reference will be made to these other social science influences as appropriate. The social turn can be seen as a reaction to psychologically and pedagogically oriented approaches, well characterized by Goodman's (1985) psycholinguistic approach. The social turn thus involved a turn away from questions of instruction and toward a consideration of literacy

2 SOCIOLINGUISTIC STUDIES OF LITERACY

in its social context and thus its contexts of use: from acquisition theories of literacy to use theories of literacy. Ironically, however, the first major study in this new approach which investigated literacy as social practice, undertaken among the Vai in Liberia, was entitled *Psychology of Literacy* (Scribner & Cole, 1981).

Baynham and Prinsloo (2009) identify a *first generation* of empirical literacy studies, among which are Scribner and Cole (1981) as well as Scollon and Scollon (1981), Heath (1983), and Street (1984). Street memorably contrasted ideological and autonomous models of literacy, arguing against writers such as Goody (1981) and Ong (1982), who assumed large-scale consequences of literacy in human development. His arguments brought an influential strand of critical anthropology to bear on literacy studies which somewhat diverted attention from Hymesian EoC for nearly two decades, although there are currently indications of its resurgence. Of the above, the work of Scollon and Scollon and Heath were the most clearly influenced by EoC. Key theoretical constructs were the *literacy event*, defined as “occasions in which written language is integral to the nature of participants’ interactions and their interpretative processes and strategies” (Heath, 1983, p. 50), and *literacy practices*. The literacy event can be easily identified empirically in terms of Hymes’s SPEAKING framework, the idea of the literacy practice is more challenging, drawing as much on social theory such as critical anthropology as on sociolinguistics as such. On literacy as practice, Barton and Hamilton write:

literacy is best understood as a set of social practices; these can be inferred from events which are mediated by written texts. . . . literacy practices are patterned by social institutions and power relations and some literacies become more dominant, visible and influential than others. (1998, p. 7)

Social theory of various sorts brought questions of power, dominance, and inequality to the fore, ensuring that literacy studies took a critical perspective on the social order, linking with activist perspectives on education (both school and adult) for which literacy was also a crucial issue.

A *second generation* of literacy studies brought to bear the methodologies and theoretical constructs of these earlier studies in a series of empirical studies, typically focusing on vernacular or local literacies (Prinsloo & Breier, 1996; Barton & Hamilton, 1998; Gregory & Williams, 2000; Martin-Jones & Jones, 2000). Prinsloo and Breier’s Social Uses of Literacy (SoUL) project examined the literacy practices of the disenfranchised in South African townships; Barton and Hamilton undertook a longitudinal study of the everyday, in their term local, literacies in Lancaster and the UK; Martin-Jones and Jones brought together research into literacy in multilingual settings; and Gregory and Williams conducted a study of literacy based on long-term ethnographic engagement with the Bangladeshi settlement in East London, notable for its emphasis on the interaction of home and school literacies in the learning lives of children.

Third-generation literacy studies (e.g., Baynham & Prinsloo, 2009) demonstrate a significant diversification of the range of topics and issues addressed. There is a problematization of the “local” in the context of a pervasive trans-localism, contrasting with the sense of place implicit in some earlier studies (see Brandt & Clinton, 2002). There is a return to pedagogical questions, eschewed in the earlier studies, whether in the focus on home-school interactions in the literacy lives of children, or the role of academic literacies in higher education (e.g., Ivanic, 1998; Lillis, 2001). There is a recognition of the impact of new technologies and electronic means of communication on the shaping of literacy practices (Warschauer, 1999) and a recognition of the impact of the visual and other modalities on literacy (Kress, 2003). Last but not least, there is recognition that a social account of literacy needs to be complemented by a cognitive account (Gee, 2000). We will now consider these developments thematically.

Academic Literacies

Academic writing has been a subject of study from a number of perspectives (for an overview, see Lea & Stierer, 1998), most notably those taking a linguistic angle in work on English for academic purposes and genre studies (i.e., writing as text; Swales, 1990). The academic literacies approach (Ivanic, 1998; Lillis, 2001) advocates a focus on both *texts and practices*, emphasizing writing (as it has primarily focused on writing) as constructed in specific disciplinary and institutional contexts, informed by particular ideologies and values, the apprentice academic writer can be understood as a legitimate peripheral participant in the academic community of practice (Wenger, 1998), learning the “ways with words” of a particular subject of study. Rather than a generic academic skill, academic writing is seen as highly diverse, shaped by the individual disciplines and subject areas. Different perspectives, influenced by different understandings of institutional power and student agency, emphasize the student writer as apprenticed into the academic community, as legitimate peripheral participant, or as critically appropriating new styles of writing. Key illustrative issues have concerned the social construction of plagiarism, academic literacies and identity, and the impact of disciplinarity and interdisciplinarity on writing practices.

Literacy and Pedagogy

It should be recalled that the social turn in literacy studies was initially a move away from a focus on pedagogy and literacy instruction. In a sense this is too important a topic to be long neglected, and researchers such as Maybin (2004) apply the insights of the social turn in literacy studies to school-based literacy. The work of Freebody on schooled reading represents a continuing strand of research which goes back to the focus on critical reading pedagogy in Baker and Luke (1991). A number of recent publications have signaled a return to questions of pedagogy (e.g., Pahl & Rowsell, 2005; Street, 2005; Barton, Ivanic, Appleby, Hodge, & Tusting, 2007). The papers collected in Street (2005) are grouped into a focus on *early years* (e.g., Stein & Mamabolo, 2005, on early literacy practices in a South African school), *adolescent years* (e.g., Oldham, 2005, on literacy and media in secondary schools in the UK), and *adult literacies* (e.g., Leung & Safford, 2005, examining the literacy practices of nontraditional students in higher education). The study reported in Barton et al. (2007) investigates the relationship between learners’ lives and their engagement with learning opportunities. Ivanic (2009) reports on a study which applied a literacy studies research approach to examine the role of literacy practices in the vocational curriculum. The literacies of a college student on a vocational course involve: literacies for being a student, such as for registration procedures; literacies for learning; literacies for assessment; and literacies for imagined futures, such as work placements. The study examined the interrelationship between the students’ vernacular, everyday literacies and literacies for learning, identifying areas for fine-tuning in the vocational curriculum to enable students to draw on their vernacular literacy practices.

Home School Literacy Studies

As mentioned above, Gregory and Williams (2000) is a study in which the interactions between home and school literacies are examined. This was, it should be recalled, a primary driver of the ethnographic work undertaken by Shirley Brice Heath and her students written up in *Ways With Words*. In Chapter 7, Gregory and Williams analyze “playing school” interactions at home between older and younger siblings and are able to show a high degree of similarity between the strategies employed by the older sibling playing

4 SOCIOLINGUISTIC STUDIES OF LITERACY

teacher and the actual reading teacher. Cruickshank (2006) examines the home and school literacies of Lebanese teenaged boys, his longitudinal ethnographic fieldwork enabling him to track the emergence of the computer as a site of literacy activity in the home. Street (2005) and Purcell-Gates (2007) both bring together case studies of literacy in diverse home and school settings. A strand of this work is developed by Freebody (Freebody & Freiberg, 2008) drawing on ethnomethodology and conversational analysis, research that addresses the challenging question posed by Heap (1991): "What counts as reading?"

Multimodal Literacies

One of the developments in the last two decades that has further problematized the question of what counts as reading is the notion of multimodality. To the extent that literacy studies treat as important the interaction between spoken and written language in literacy events, it is already multimodal, but the concept of multimodality is particularly associated with the shift to the visual that Kress and van Leeuwen (2001) and others have detected in communication practices. This is particularly in evidence in relation to the digital shift in literacy and in this context the dimension of multimodality will be very relevant.

Digital Literacies

Studies of digital (Lankshear & Knobel, 2008; Gillen & Barton, 2010) or electronic literacies (Warschauer, 2009) focus on the impact of the introduction of new technologies on literacy practices. Kress (2010, p. 6), in a contribution to Gillen and Barton (2010), argues for four dimensions involved in this impact: (a) an increase in the multimodality of communication; (b) a shift from page to screen; (c) changes in social structures and social relations, in particular changes in authority and gender structures; and (d) transformation of the traditional post-Gutenberg medium of book and mode of writing to the screen as medium and the image as the dominant mode. Added to these are implications for transnationalism. Lam's research (e.g., Lam, 2004) shows how online chat rooms create an environment for multilingual online communication that redraws the boundaries between spoken and written language as well as between language and national boundaries, creating, in effect, transnational spaces for transnational literacies (see below). It is thus becoming increasingly unviable to conceptualize literacy without taking into account the dynamic changes in the means of communication, their impact on literacy practices, indeed the blurring of boundaries between spoken and written language that are involved. Warschauer (2009) investigates this through the online communication practices of young Egyptian professionals, finding a preference for English in Web browsing and formal e-mails, but with switching between the use of English of colloquial Egyptian dialect in Romanized script in informal e-mail communication.

New opportunities afforded by interactive Web 2.0 environments such as blogging (Davies & Merchant, 2006), Facebook, and Skype are greatly increasing the opportunities for authoring online, albeit within the constraints of the particular platform, as well the amount of visual material that is available, with some sites such as Flickr being built around the sharing and tagging of photographs.

Trans-Local Literacies

One of the emphases of Street's ideological model of literacy lies in its insistence on the contextually situated, as it were local, nature of literacy, in contrast to the autonomous

model which treats literacy as a neutral, transferrable skill, with extensive benefits and impacts in the project of modernity. We have seen how this emphasis on the contextualization of literacy gave rise to a number of studies which examined literacy in local contexts, emphasizing its situatedness, particularly in relation to dominant, school-based constructions of literacy. A challenge to this perspective, as articulated in Brandt and Clinton (2002) and Luke (2004), is that the local perspective on literacy ignores the dynamic interactions of local with global flows and processes. A response to this challenge gives rise to an emerging focus on transnational or trans-local literacies (Warriner, 2007) or, as Kell (2009) argues, for a trans-contextual approach. All of these highlight the fact that literacy is not just situated but also travels from site to site, and context to context, both within and across borders. Kell (2009) reports a study of the literacy practices involved in building a house in the South African township of Khayaletu, identifying literacy practices that, while focused on the local context of the site where the house was to be built, also brought in literacy practices at community, local council, and provincial scales. Such an analysis accounts for the simultaneity and interactivity of much contemporary literacy activity, while retaining the insight that “the global is also profoundly local” (Baynham, 2004, p. 289). McGinnis, Goodstein-Stolzenberg, and Salianni (2007) examine the hybrid, online textual practices of young people who are bringing together linguistic and ethnically diverse identities in the writing or authoring spaces which they appropriate on the Web. Such authoring spaces exploit the current affordances of digital literacies, but are also clearly multimodal in character. While retaining the focus on situatedness which has been such a crucial aspect of the social turn in literacy studies, transnational, trans-local and trans-contextual studies emphasize the complex interactions between phenomena of different scales: the measuring of the dimensions of a planned house on the ground, the regulations on such dimensions as they exist in a council planning office. Such studies extend the ability to capture the complexity of literacy studies, vastly increasing the ability to deal with the operations of power for example, without departing from literacy studies key premises.

Literacy and Theories of Learning

The social turn in literacy studies, as pointed out above, was initially a turn away from questions of pedagogy and learning toward questions of use. Just as questions of literacy pedagogy are too important to be long neglected, so are questions of literacy learning. Rather than going back to the psycholinguistic approach of the 1980s, literacy studies have sought to identify approaches to learning congruent with a social perspective. Gee (2000) identifies a number of these: sociocultural theory, activity theory (Engstrom, 1990), and situated cognition theory (Lave & Wenger, 1991). These approaches provide a basis for the timely reintroduction of the dimension of learning into literacy studies and are likely to be a productive theme for continuing work.

Conclusion

In this entry sociolinguistic approaches to literacy have been located within a broader social turn, taking in influences from sociology and anthropology and other social science disciplines, while identifying a clear sociolinguistic influence, derived from the ethnography of communication. Building on early work in the 1980s and 1990s, current work is influenced by a number of factors such as the increasing salience of multimodal communication, the dramatic increase in digital communication, and the no less dramatic increase in global interactivity, and transnationalism, which have forced a reconsideration of the question

"What counts as literacy?" and a refocusing of what is meant by local in a globalized world. Initially a turn away from pedagogical and learning orientations to literacy, there is currently an increased emphasis on both these aspects, albeit from a social perspective. At present it seems as if the theoretical and methodological frameworks developed in literacy studies are sufficiently robust and flexible to respond to the challenges of these new literacy landscapes, indeed it is in the exploration of these newly emerging literacy environments, in a kind of crucible of semiotic change in progress, that the most exciting current work is being done.

Sociolinguistic Surveys in Language Planning

PAULIN G. DJITÉ

There are a number of useful approaches to collecting data in language planning (Fishman, 1974; Kloss & McConnell, 1974–84; Haugen, 1988; Breton, 2003). Of these, sociolinguistic surveys have pride of place, when it comes to small, medium, or large-scale research projects (Cooper, 1980; Casad, 1993; Baker, 2003).

The purpose of sociolinguistic surveys is to assess the linguistic and sociolinguistic situations in one or a number of speech communities within a locality, a region, or a state, through a set of questions seeking to find out who speaks what language to whom, under what conditions and for what purpose(s) (Kaplan & Baldauf, 1997). Both individuals and speech communities often control several languages or varieties of languages, which they use for specific objectives, with clearly identified audiences. Sociolinguistic surveys aim to collect basic information regarding speech varieties, their speech areas, and their relationships. They ask questions eliciting judgments on differences or changes in language use and can help measure the ability of individuals within a speech community to speak, understand, or both speak and understand another language, the vitality of these languages, the differences and similarities in speech of communities that speak related speech forms, noting comprehension or collecting details of linguistic form, and people's attitudes to different languages or varieties of languages (Koenig, Chia, & Povey, 1983; Salami, 1986). They are intended to answer questions such as:

1. How many languages or speech varieties are there in a given community?
2. Where are they spoken and by how many people?
3. What is the level of inter-comprehension among speakers of the various speech varieties?
4. Are the language varieties spoken in the community healthy, or are there indications of language shift?
5. What are the attitudes within the community toward the other speech varieties and toward their speakers?
6. What speech variety(ies) or language(s) is officially promoted?

They are also intended to answer question such as: In what language(s) do people in a particular speech community go about the activities of everyday life, such as socializing (e.g., speaking to parents, peers, siblings, children, partner, other relatives, workmates)? In what language(s) do they participate in various other social activities, such as shopping, going to church or to the mosque, listening to the news, reading, learning (e.g., primary, secondary and university education)?

The answers to these questions will help form a general picture of the language situation in a speech community, in terms of language comprehension, language viability, and language attitudes. It is not uncommon for individuals to socialize in one language and work in another, or to learn in a mother tongue at primary school level, then in a regional, official, or both regional and official language at secondary and tertiary levels (Kaplan & Baldauf, Jr., 1997).

2 SOCIOLINGUISTIC SURVEYS IN LANGUAGE PLANNING

Sociolinguistic surveys involve some conceptualization of the language/ethnic make-up of a speech community, its history, as well as some notions of the political and economic forces at work within it. They also involve the formulation and design of appropriate data collection instruments (i.e., questionnaires, interviews, observation, or all three of these). The methods used in sociolinguistic surveys depend on the questions the researchers are trying to answer (questionnaires, group and individual interviews, retelling of stories, direct observation, etc.) and the reliability of the results varies according to the method used and the rigor with which it is applied. It is important, for instance, to work out from the start whether the research instruments will be written or not, and in what language(s). It is also important to determine the best way to administer the data collection instruments; will a questionnaire, for example, be posted to respondents and returned by post, or will it manually distributed and collected?

The research instruments often need to be refined along the way, in terms of length, appropriateness, relevance, and significance of parameters. Finally, the data will need to be collated and processed regularly and in a timely manner, and in several formats (e.g., computerized numerical format, interview notes, secondary data from documentary evidence, etc.) Selection of the research instruments to be used is based on the quality of the data needed on the one hand, and the time and cost that can be invested in a survey on the other.

Depending on their scale and objectives, sociolinguistic surveys may last from a few days to as long as three to four years. Long-term sociolinguistic surveys (i.e., lasting three to four years) require extensive presurvey organizational planning, in order to ensure an adequate research team is assembled, and adequate resources and time are provided to achieve the aims of the survey. They also often require the collection of preliminary data, in order to inform the design of the survey instruments (i.e., questionnaires, interview format and contents, etc.).

Sociolinguistic surveys can be conducted from various perspectives, for example, anthropological, ethnographic, historical, and so forth. The latter is most valuable for tracking change over time and is important, as the historical development of language use and its interaction with other cultural elements in a speech community is key to understanding the role and place of a particular language or language variety (Hornberger, 2005). Historical evidence is always crucial for testing hypotheses about language-related issues. The anthropological perspective is mainly concerned with the field study of language and shows what aspects of language(s) are used for which purposes. This approach is useful in the development of terminological equivalence. Approaching sociolinguistic surveys from the perspective of the ethnography of communication helps understand the sociolinguistic resources available in particular speech communities, and the ways in which native speakers enact communicative acts in a variety of situations.

Sociolinguistic surveys are usually a first step in a complex process that can include a (survey) report. This report may contain recommendations, which may in turn lead to a series of policy decisions, and eventually an implementation plan to resolve a particular issue(s) raised in the report. The results of language surveys are used for a variety of purposes (e.g., implementation of educational programs, language development work, status planning, etc.).

Sociolinguistics: Mixed Methods

STEPHEN CALDAS

Mixed methods research incorporates both quantitative and qualitative research techniques, and provides a broader, more rounded, and multifaceted perspective on the complex reality of social settings than either quantitative or qualitative approaches alone (Teddle & Tashakkori, 2009). A mixed methods approach can be especially illuminative at the level of the case study, which has traditionally relied only on qualitative techniques like observation and field notes. However, with the collection of enough longitudinal numerical data, quantitative analysis can be used to corroborate qualitative findings in a linguistic case study. This entry provides examples of how the author and his wife used both quantitative and qualitative data analysis in their 19-year mixed methods case study to rear their three children to be French–English bilingual, biliterate, and bicultural. In 1979, monolingual English-speaking Stephen met and fell in love with monolingual French-speaking Suzanne from Quebec, Canada, during her three-weeks of summer study abroad in Stephen's home state of Louisiana. Following their marriage a year later, and much effort to learn each other's language, the young couple decided to rear their yet-to-be-born children simultaneously in both languages. They documented their efforts in both qualitative and quantitative studies published in a series of articles (Caldas & Caron-Caldas, 1992, 1997, 1999, 2000, 2002; Caldas, 2008) and a book (Caldas, 2006).

At the beginning of our bilingual project, before our first child, John, was born in 1985, we determined that Stephen would address him only in his native language (English), and Suzanne would address him only in her native language (French). This approach is referred to as "one parent, one language" (Döpke, 1992). When John was 18 months old, we modified our family language policy and both began to address John only in French. We continued this policy with the birth of identical twin girls Valerie and Stephanie in 1987. For the duration of the study our family spent academic school years (10 months) in southern Louisiana, and summers (June and July) in an all-French-speaking community in the province of Quebec, Canada. The twins attended a French immersion school program in Louisiana from the second through the seventh grades. John only attended a half year in a French immersion program in Louisiana (during the fourth grade). All three children attended approximately six weeks of all-French elementary schooling in Quebec, Canada.

Qualitative Methods

The authors of this study were participant observers, a qualitative research technique developed by anthropologists like Margaret Meade (1928) and first applied in early sociolinguistic research by Ronjat (1913). The parents were active participants in the family while at the same time trying to understand and explain the sociolinguistic dynamics they were observing.

As a participant observer in constant consultation with his wife, the lead author kept careful ethnographic field-note observations documenting how his children were reading, writing, and speaking French and English. He began systematically writing field notes when John was 9;3 and the twins were 7;3. These field notes spanned 11.5 years, though the bulk of the entries were written based on observations during the nine years from 1994 to 2003.

2 SOCIOLINGUISTICS: MIXED METHODS

The field-note entries made references to which languages the parents and children were speaking, what they actually said, who they said it to, when they said it, and the family linguistic context at the time. The notes were for the most part written on a computer by the author in the early morning or late at night. The author also jotted down notes on paper he carried with him. The entries were written based on observations both in the family residences in Louisiana and Quebec, and when traveling together with the children in the USA, Canada, Mexico, and Europe. The following entry, written in Louisiana when John was 9;3 and the twins 7;3, is a typical entry in terms of style and content:

Today was the first day of school for the three kids. Both Suzanne and I noticed that after school all the children spoke only in French. In response to my question (in French) of how her day went, Valerie volunteered that she at times had trouble speaking in English. John, overhearing her, immediately jumped in and said, "*C'est vrai, lorsque je parlais anglais des fois j'ai dit 'oui, parce que,' sans penser.*" ["It's true, when I spoke English sometimes I said (in French) 'Yes, because,' without thinking."]

The author did not formally code common themes or words in his field notes, as some qualitative researchers do. Rather, he used the field notes as a historical narrative which provided rich description over a long period of time, which he could compare with the quantitative data (discussed below). Whereas this approach seemed to work for our project, coding is an important qualitative tool that could have yielded even more important insights had it been employed.

In an effort to have the children describe their perceptions of what it was like to develop as a bilingual in their two monolingual cultures, the author created a qualitative/quantitative instrument written in English which he termed the "bilingual self-perception survey." The survey included seven open-ended questions soliciting written information from the children about how they felt being bilingual around their friends in both monolingual English-speaking Louisiana, and monolingual French-speaking Quebec. The children completed the surveys on their own (and alone) at three different times spanning eight years from early to late adolescence and into early adulthood. The author analyzed, synthesized, and compared the children's responses over time in an effort to demonstrate how the children's self-perceptions of their bilingualism changed over the course of their adolescence (Caldas, 2008).

Quantitative Methods

The author also constructed two almost identically worded quantitative surveys, written in French, to longitudinally measure the children's French proficiency. One survey was completed by the children themselves at the same three times as they completed the bilingual self-perception survey. The other was completed by the children's native French-speaking teachers and camp counselors over a four-year period (5 teachers and counselors altogether for John and 10 for the twins). Each French-proficiency survey had 10 questions gauging the children's abilities to read, write, speak, understand, and function in French compared to a native French-speaking child of the same age. Each question was followed by a five-point Likert scale with values ranging from 1 (very inferior) to 5 (very comparable). As an overall global measure of French proficiency, the author calculated an overall average proficiency rating for each child by adding all the Likert values together and dividing by the total number of survey questions (10). This is a valid approach, since each question was phrased such that the higher the Likert value, the greater the proficiency in some aspect of French. A perfect score would be 50 (10×5). The responses to this survey allowed for a more objective measure (other than the authors' perceptions) of the overall French proficiencies of the children based on the observations of knowledgeable educators, as well as the children's own self-perceptions.

The author conducted paired samples *t*-test comparisons of each child's overall French proficiency scores at Times 1–3. This allowed for a determination of whether the children's overall perceptions of their abilities in French were changing over time. The ability to determine whether there are statistically significant differences between mean scores when using *t* tests is a function of sample size: The larger the *N* (or number of items on the survey, in our example), the more likely one will find a statistically significant difference, if there is a meaningful difference to be discovered. By way of example, a determination was made that Valerie's and Stephanie's perception of their overall abilities did not change significantly from Time 1 (age 10;10) to Time 2 (age 16;1), though John's perceptions of his own abilities did indeed significantly increase from Time 1 (age 12;10) to Time 2 (age 18;1). Also, the children's overall scores could be compared to one another, which allowed for determinations such that all three children's overall perceived French proficiency increased from Time 1 to Time 3, but John's score increased the most.

The author also correlated all of the children's French proficiency responses with each other at Time 1, Time 2, and Time 3 in order to tell if the children's ratings of the various dimensions of French proficiency covaried in similar ways. As with *t* tests, obtaining a statistically significant correlation coefficient (Pearson's *r*) is likewise a function of *N* (i.e., the number of survey items). This procedure allowed for a determination that Valerie's and Stephanie's responses at Time 1 (age 10;10) were, somewhat surprisingly for identical twins, not significantly correlated. However, John's and Stephanie's responses at Time 1 were positively correlated ($r = .701, p < .05$). That is, John and Stephanie tended to rate themselves higher and lower on the same items at Time 1, while the twins' responses at Time 1 were not statistically related to each other. (The children's French proficiency survey responses were also correlated with the average scores of their teachers.)

As a measure of the children's language dominance (as opposed to "proficiency" or "preference"), the author used Edelman's contextualized measure of the degree of bilingualism (Edelman, 1969). Edelman's measure is used to determine in which language a bilingual is dominant in three areas of life—the home, the school, and the neighborhood (denoted by "E"). The measure was employed by asking each child to name as many things as he or she could think of in a 45-second interval, first in French and then in English, in each domain (the order of the languages was alternated with each administration). For example, the child was asked, "Name as many things as you can think of that have something to do with your school." The author took a pencil tally of each word the child uttered. The author administered this instrument separately to each child on 20 occasions over a 27-month period beginning when John was 10;8 and the twins were 8;8. An Edelman's coefficient is a ratio of French to English dominance. Values can range from 0 to 1, with ratios greater than $E = .5$ indicating French dominance and ratios less than $E = .5$ indicating English dominance. The following formula was used to create the ratio:

$$\left[\left(\frac{\text{number of French words (tokens)} - \text{number of English words (tokens)}}{\text{larger of the two}} \right) + 1 \right] \div 2$$

The reader is encouraged to insert the actual figures below for John into the Edelman's formula and verify that the *E* values presented are correct:

John's French/English utterances on February 4, 1996 used in Edelman's coefficient

<i>Domain</i>	<i>French</i>	<i>English</i>	<i>E</i>
Home	30	30	.50
School	21	25	.42
Neighborhood	20	25	.40

Figure 1 John's shifting bilingual dominance in three domains © Stephen Caldas

The Edelman's coefficients for longitudinal trends were analyzed and the coefficients were correlated (since an N of 20 was sufficiently large) in each of the three domains for each child, and between the three children. An average Edelman's coefficient was also created for each child at each administration by averaging the three domains. There was a statistically significant correlation between the neighborhood and home domains for both John ($r = .53, p < .05$) and Stephanie ($r = .48, p < .05$). In other words, during administrations when both children had high Edelman's ratios in the neighborhood domain, both children also tended to have high ratios in the home domain. Thus, thinking in French in one area of life may positively influence French thinking in another area (see Figure 1 for John's dominance trends).

Correlating the children's Edelman's coefficients with each other in each domain revealed a moderate positive relationship between John and Stephanie in the home domain ($r = .55, p < .05$), and an even stronger relationship between Stephanie and Valerie ($r = .59, p < .01$). What this may indicate is that the children's fluctuating bilingual dominance was likely being influenced by the home domain in a similar way over the 27-month period.

An overall global average measure of bilingual dominance was created for each child in each domain, and in all three domains averaged together. For each child, paired samples t tests were run comparing the overall average Edelman's coefficient in each domain to determine where there were statistically significant differences. For example, t -test comparisons revealed that there was a statistically significant difference between the overall ratio of French to English spoken by John in the home domain ($E = .24$) compared to the school domain ($E = .19$). Thus, though he was English-dominant in both domains, he was significantly more English-dominant in the domain of schooling.

The global ratios revealed that no child was overall French-dominant in any domain over the 27-month period, and that Valerie had the highest overall ratio ($E = .45$), followed by Stephanie ($E = .42$) and John ($E = .40$). Also, all three children were most French-dominant in the home.

Audiotaping

The author began six years of systematically audiotaping family dinnertime conversations on an almost weekly basis when John was aged 9;7 and the twins were 7;7. The audiotaping sessions, which were 10 minutes in length, were conducted in both the Louisiana and the Quebec residences. The sessions almost always included all five family members, and never included any non-family members.

The author and his wife listened to five minutes of every taped session over the six years ($N = 68$ total), and separately tallied the number of French and English words (tokens) they heard the father, mother, John, and twins (together) speak at each dinnertime session.

Figure 2 Bilingual preference ratios (BPRs) of John and twins, superimposed by age 9;7 through 13;7 © Stephen Caldas

(The twins were counted as one person because their voices were too similar to be clearly distinguished.) Then, to minimize error, the tallies by each parent were combined for each person and divided by two to create an average number of French and English words spoken by each family member. Monthly averages were created for everyone.

The author used the Edelman's formula (given above) to create a ratio of spoken French to English words at each taped session for each family member. This index, which we have termed the bilingual proficiency ratio (BPR), is a measure of bilingual proficiency, and is indicative of the degree to which the children and parents preferred to speak French or English (Caldas & Caron-Caldas, 2000). As with the Edelman's coefficient, values can range from 0 to 1, with greater numbers indicating a greater preference for French, values of .5 indicating an equal preference for either tongue, and values of less than .5 indicating a preference for English. This metric was useful for many purposes, including correlating family members' responses. However, it was especially useful for comparing and tracking longitudinal trends in shifting language preferences over the most critical years of adolescence in both Quebec (where John's preference was always for French) and Louisiana (where John's preference was increasingly for English; see Figure 2 for John's shifting BPRs).

As an indicator of changing bilingual preference, the BPRs of the children all indicate very clearly that their preferences for speaking French were highest in early/pre-adolescence, and plummeted beginning about age 10;5 in the Louisiana context. However, in the Quebec family context, the children's BPRs remained very high throughout the study, indicating a decided preference for speaking French around the family dinner table while in Canada.

Conclusions

In sum, using mixed methods allowed for the triangulation of qualitative and quantitative data to show the effect of sociolinguistic context on the children's developing bilingual identities and language preferences. The qualitative data give a feel for the children's changing perceptions of their bilingualism as they moved into and through adolescence. The quantitative data corroborate with numbers and statistical significance what we observed and recorded in our field notes.

Sociolinguistics: Quantitative Methods

JACK GRIEVE

Introduction

Variationist sociolinguistics was one of the first branches of linguistics to adopt a quantitative approach to data analysis (e.g., Fischer, 1958; Labov, 1963, 1966, 1969; Wolfram, 1969). While the earliest variationist studies did not usually employ statistical methods, they were concerned nonetheless with identifying a relationship between the values of a quantitative linguistic variable and the levels of a categorical social variable. The linguistic variables analyzed in traditional variationist studies represent an alternation between two distinct linguistic forms (or variants) that convey the same basic meaning (Labov, 1972; Wolfram, 1991). Examples of linguistic variables include sets of alternative pronunciations, equivalent grammatical constructions, and synonymous words. The basic goal of variationist research is to identify the social factors that influence the choice between the variants of linguistic variables. For example, Labov (1966) found that the likelihood of pronouncing /r/ following vowels was directly related to the socioeconomic status of speakers in New York City. Labov also found that the pronunciation of /r/ was related to age, with younger speakers being more likely to pronounce /r/ than older speakers in the upper middle class, but with older speakers being more likely to pronounce /r/ than younger speakers in the lower middle class. Labov argued that the pronunciation of /r/ was most common in the language of the younger upper middle class because this pronunciation was in the process of becoming the more prestigious form, but that this pattern was reversed in the language of the lower middle class because older speakers were more likely to be aware of the prestige associated with the pronunciation /r/ than younger speakers, and were thus more likely to adopt the innovation, revealing their social aspirations.

While early variationist studies focused on simple relationships between the value of a linguistic variable and the value of a social variable, over time more advanced methods for the analysis of linguistic variation were developed. Since the 1970s, the most common statistical method in sociolinguistic research has been logistic regression, which is used to test if the alternation between the variants of a linguistic variable is predicted by various aspects of the social background of a speaker, while also taking into consideration the effect of the linguistic environment in which each token of the variable is produced (Cedergren & Sankoff, 1974; Sankoff & Labov, 1979). For example, Ashby (1981) used a logistic regression to analyze variation in the use of the negative particle *ne* in French, which can optionally be deleted, as negation is marked redundantly elsewhere in the sentence. Ashby found that age, social class, and gender all affect negative-particle deletion in French, with the young, the lower middle class, and women being more likely to delete *ne*. Sociolinguistic research of this type has repeatedly shown that linguistic variation is correlated with numerous factors related to the social background of speakers, including age, gender, ethnicity, and socioeconomic status, as well as various linguistic factors.

While logistic regression is a standard technique in sociolinguistics, no form of regression analysis is common in regional dialectology, the precursor and now a subdiscipline of the field. Indeed, one of the main factors that led to modern sociolinguistics superseding traditional dialectology was its adoption of a statistical approach to data analysis. Traditional

dialectology did not employ statistical methods, but relied instead on the subjective analysis of categorical display maps plotting where the different variants of a linguistic variable occurred across a region (e.g., Wenker, 1881; Gilliéron, 1902–10; Kurath, Hansen, Bloch, & Bloch, 1939–43; Kurath, 1949; Kurath & McDavid, 1961). Modern American dialectology (e.g., Pederson, McDaniel, & Adams, 1986–93; Carver, 1987; Labov, Ash, & Boberg, 2006) is still largely based on subjective approaches to data analysis; basic statistics are computed, but the identification of regional patterns is still based primarily on the judgment of dialectologists. In European dialectology, a quantitative approach known as dialectometry (Séguy, 1971, 1973; Goebel, 1982, 2006; Nerbonne et al., 1996; Nerbonne & Kleiweg, 2003, 2007) has become common, but it involves initially aggregating the values of numerous linguistic variables and thus offers no direct method for testing if an individual linguistic variable exhibits a regional pattern, in the way that logistic regression allows for social patterns to be identified in the distribution of a linguistic variable. The reason that regression has not become a standard tool in regional dialectology is because regional linguistic patterns are not necessarily linear. A linear pattern is possible, such as the gradual change in the value of a linguistic variable from the southwest to the northeast of a region; however, non linear patterns are also possible, such as the clustering of a variant in the center of a region or the presence of numerous smaller clusters across a region. While linear regional patterns could be identified in the distribution of a linguistic variable by conducting a regression with longitude and latitude as predictors, non linear patterns, which seem to abound in regional dialectology, cannot be easily identified using any form of linear regression.

This entry presents a solution to this problem—a quantitative method for identifying significant linear and non linear regional patterns in the values of an individual linguistic variable measured across a series of locations. The method is based on two measures of spatial autocorrelation: global Moran's *I* and local Getis-Ord *G_i^**. These statistics allow for significant regional clusters to be identified in the spatial distribution of a linguistic variable. Moran's *I* identifies variables that exhibit significant levels of spatial clustering, while Getis-Ord *G_i^** identifies the location of high- and low-value clusters. These statistics are used here to test if four measures of *not* contraction are regionally patterned in a corpus of letters to the editor representing the language of 200 cities from across the United States. In addition to illustrating the use of these statistics, this study also demonstrates that regional linguistic variation exists in written Standard American English. This is an important finding in and of itself, as it is generally assumed that regional linguistic variation, and sociolinguistic variation in general, does not exist to a significant degree in the written standard, but only in writing that directly represents the spoken vernacular (Schneider, 2002).

Data Collection

This study is based on a corpus of letters to the editor representing the language of 200 cities from across the United States. The letter-to-the-editor register was selected for analysis because it is a variety of written Standard English that is particularly suitable for a study of regional linguistic variation: Letters to the editor are annotated for their author's place of residence, written by a large number of authors from across the United States, published frequently, and made freely available online. The corpus of letters to the editor was compiled by downloading letters published between 2000 and 2008 from the online archives of hundreds of American newspapers. Once downloaded, each letter was sorted into a city subcorpus based on its author's place of residence, as indicated in the byline of the letter. City subcorpora were then formed for the 200 cities whose residents had contributed at least 25,000 words of text. The corpus includes cities in every state in the

contiguous United States, including most major cities. The entire corpus contains 154,269 letters written by 126,422 authors totalling 25,794,656 words.

Data Analysis

Four measures of *not* contraction were analyzed across the 200 city subcorpora: *not* contraction following copular and auxiliary *be* (e.g., *he is not/isn't there*), auxiliary *have* (e.g., *he has not/hasn't spoken*), auxiliary *do* (e.g., *he does not/doesn't mind*), and modals (e.g., *he will not/won't mind*). The variables were computed by calculating the proportion of contracted *not* relative to full *not*—see Equation 1, where f_{cont} is the frequency of the contracted form and f_{full} is the frequency of the full form.

$$(1) \quad v = \frac{f_{cont}}{f_{cont} + f_{full}}$$

Each contraction variable was measured in this way for each city subcorpus.

In order to determine if each measure of *not* contraction exhibits a significant regional pattern, each variable was subjected to an analysis of spatial autocorrelation—a measure of spatial dependency that quantifies the degree of spatial clustering in the values of a variable (Cliff & Ord, 1973, 1981; Odland, 1988). First, an analysis of global spatial autocorrelation was conducted using global Moran's *I* (Moran, 1948; Odland, 1988). The value of Moran's *I* ranges from -1 to 1 , where a negative value indicates that neighboring data points tend to have different values, a value approaching zero indicates that neighboring data points tend to have random values, and a positive value indicates that neighboring data points tend to have similar values (Odland, 1988). The formula for calculating global Moran's *I* is provided in Equation 2 (Odland, 1988), where N is the total number of locations, x_i is value of the variable at location i , x_j is value of the variable at location j , $\bar{x}$ is the mean for the variable across all locations, and w_{ij} is the value of the spatial weighting function for the comparison of location x_i and x_j .

$$(2) \quad I = \frac{N}{\sum_i \sum_j w_{ij}} \frac{\sum_i \sum_j w_{ij} (x_i - \bar{x})(x_j - \bar{x})}{\sum_i (x_i - \bar{x})^2}$$

The spatial weighting function is a set of rules that assigns a weight to every pair of values in the distribution of a variable based on proximity. In this study, a standard binary weighting function with a 500-mile cutoff distance was used, so that comparisons between locations within 500 miles of each other were given a weight of 1 and all other comparisons were given a weight of 0. A 500-mile radius was selected so that locations traditionally classified as being within the same dialect and cultural regions could be compared. In order to determine the significance of the computed value for Moran's *I*, a standardized *z* score was obtained, under the assumption of randomization (see Odland, 1988). The *z* score was then interpreted as significant if it was larger than or equal to 2.50—the *z* score corresponding to a two-tailed .0125 alpha level, which was selected based on a Bonferroni correction for four variables. A significant positive *z* score indicates that neighboring locations have similar values at a greater degree than would be expected by chance.

In addition to measuring global spatial autocorrelation, which tests whether a variable is regionally patterned, local spatial autocorrelation was measured in order to identify the location of high- and low-value clusters in the spatial distribution of each variable. Local spatial autocorrelation was measured using local Getis–Ord *Gi** (Ord & Getis, 1995). Unlike global Moran's *I*, which returns one value for a variable indicating the degree of regional clustering, local Getis–Ord *Gi** returns a *z* score for each location for a variable indicating the degree to which that location is part of a high- or low-value cluster. The formula for calculating a Getis–Ord *Gi** *z* score is provided in Equation 3 (Ord & Getis, 1995).

$$(3) \quad G_i^* = \frac{\sum_j w_{ij} x_j - \bar{x} \sum_j w_{ij}}{\sqrt{\frac{\sum_j x_j^2}{N} - \bar{x}^2} \sqrt{\frac{N \sum_j w_{ij}^2 - (\sum_j w_{ij})^2}{N-1}}}$$

A significant negative Getis–Ord G_i^* z score indicates that the location is part of a low-value cluster, whereas a significant positive Getis–Ord G_i^* z score indicates that the location is part of a high-value cluster. The Getis–Ord G_i^* z score was interpreted as significant if it was larger than or equal to 2.50, based on the Bonferroni correction described above. Once computed, the Getis–Ord G_i^* z scores for each variable were then mapped in order to identify the location of significant high- and low-value clusters.

Results

Based on the analysis of global spatial autocorrelation, significant clustering was identified for three of the four measures of *not* contraction: *be not* contraction ($I = 0.039$, $p = 0.001$), *do not* contraction ($I = 0.077$, $p = 0.000$), and *modal not* contraction ($I = 0.050$, $p = 0.000$). Based on the adjusted p value, *have not* contraction was not found to exhibit significant levels of clustering ($I = 0.024$, $p = 0.033$). Maps displaying the corresponding Getis–Ord G_i^* z scores for the three measures of *not* contraction found to exhibit significant levels of global spatial autocorrelation are presented in Figures 1–3. These maps identify the location of high- and low-value clusters in the distributions of the individual variables. Based on an analysis of these local spatial autocorrelation maps, it is clear that all three variables exhibit similar regional patterns, contrasting the language of the East Coast, where *not* contraction is relatively uncommon, with the language of the rest of the United States, where *not* contraction is relatively common. However, while the low values for all three

Figure 1 *Be not* contraction Getis–Ord G_i^* z scores

Figure 2 *Do not* contraction Getis–Ord G_i^* z scores

Figure 3 *Modal not* contraction Getis–Ord G_i^* z scores

measures cluster in the east, the focal areas for *do not* contraction and *modal not* contraction are in the northeast, whereas the focal area for *be not* contraction is in the southeast. The focal areas for the high-value clusters are in the Midwest for all three variables, especially the western Midwest and the northern Plains, as well as the Pacific Northwest for *do not* contraction.

Discussion

The study found that *not* contraction is regionally patterned in written Standard American English, with letters to the editor from the western United States exhibiting a higher rate of *not* contraction than letters from the eastern United States. It is surprising that a contrast between the east and the west has been identified by the autocorrelation analysis, as previous surveys have found that the contrast between the north and the south is far stronger in American English (Kurath, 1949; Carver, 1987; Labov et al., 2006). The east–west contrast is also unusual because it groups the Midwest with the west; the Midwest is generally considered to be an extension of eastern dialect regions. The results of this study show that, in terms of *not* contraction, the language of the Midwest is distinct from the language of the east coast. This finding makes sense intuitively: when asked, Americans identify a distinct Midwest dialect region (Preston, 2002), and the Midwest and the northeast can also be distinguished on historical, cultural, geographical, and political grounds (Zelinsky, 1973).

The general finding that regional linguistic variation exists in written Standard English is also an important result because it challenges the common assumption that sociolinguistic variation, including regional linguistic variation, does not exist in written standard language (Schneider, 2002). The results of this study show that this assumption is false: Regional linguistic variation does exist in written Standard English. More generally, this finding implies that regional linguistic variation is more common than has been previously assumed. If regional linguistic variation exists in written Standard English, it seems likely that regional linguistic variation exists across the range of English registers, not only in the spoken vernacular. The statistical approach to data analysis described here, particularly when coupled with a corpus-based approach to data collection, constitutes a method for identifying regional variation across a range of registers, especially in registers where regional patterns may not be as strong as they are in the spoken vernacular. This was certainly the case in the present study: If the autocorrelation statistics had not been employed, it would have been difficult to convincingly identify regional patterns in *not* contraction.

In addition to these important findings, the study also demonstrates how measures of spatial autocorrelation can be used to analyze regional linguistic variation in the values of an individual linguistic variable. In essence, the spatial autocorrelation statistics allow for regional patterns to be identified in the spatial distribution of a linguistic variable in the same way as logistic regression allows for social patterns to be identified in the social distribution of a linguistic variable. Overall, the advantages of the statistical approach are clear. It allows for an objective, unbiased, and replicable analysis of regional linguistic variation to be conducted, where regional patterns are identified based on significance testing as opposed to the judgment of the dialectologist. This not only allows for the presence of obvious patterns to be confirmed but it also allows for patterns to be identified that may have been overlooked by a subjective analysis. Arguably, identifying a variable that exhibits a regional pattern and describing this pattern is the most basic form of analysis in regional dialectology; however, until now, there has been no acceptable statistical method for conducting this analysis. In modern dialectology, the analysis of an individual linguistic variable is usually accomplished through the subjective examination of a map plotting the raw values of the variable. In modern dialectometry, the analysis of individual linguistic variables is usually ignored. The two measures of spatial autocorrelation presented here provide a statistically justified method for identifying regional linguistic patterns in the values of an individual linguistic variable.

Sociological Approaches to Translation

GISELLA M. VORDEROBERMEIER

An initial indication to the potential significance of a future “translation sociology” or “socio-translation studies” can be dated to a seminal lecture delivered by James S. Holmes in 1972, to which translation studies also owes its name (see Holmes, 1988/1972). In the intervening years sociological approaches have developed into an important field of study, which can justly claim to be more than merely another “hyphenated sociology” and which, in studying the phenomena of translation and interpreting as unique cultural techniques, has much to contribute to honing sociological concepts. It must be noted, however, that sociology—despite the claim already inherent in its origins as a discipline to be able to deal with virtually an infinite number of objects of research without being subject to any corresponding constraints—discovered translation as an object of study at a comparatively late date. In translation studies, too, a sociological point of view has only gradually gained acceptance (Simeoni, 2005; see also Wolf, 1999, 2003).

The sociological approaches which currently present themselves to the observer are in large part a product of the increasing attention paid in recent years to asymmetrical power relations, the (im)possibility of neutrality in translation and interpretation processes, and the associated perception and visibility of translators and interpreters in society at large. Important contributions come from within the discipline itself (among the important figures in this respect are Buzelin, Gouanvic, Inghilleri, Simeoni, Sela-Sheffy, and Wolf) as well as from outside it (e.g., Casanova, 2004, and some of the contributions in Heilbron & Sapiró, 2002, 2008). To date, studies on translation from a sociological point of view outweigh those which seek to bring a sociological perspective to bear on interpreting or which cover both fields of study. Arguably this has more to do with the divergences in the developments undergone by the two subdisciplines than with questions concerning the applicability of the sociological concepts that have predominated. An additional factor is that literary translation has so far attracted far more attention than technical translation. Very thorough appraisals of the state of the art in the sociology of translation in general are offered by Wolf (2007a) and—focusing primarily on research projects influenced by Bourdieu—by Inghilleri (2005).

The central aim of the sociological approaches is to render translation (and interpreting) describable and explainable as social practices, as social facts, and thus as “socially regulated activities” (Hermans, 1996). This includes examining the role of the actors in processes of selection, production, distribution, and reception of translations (Wolf, 2003; Bachleitner & Wolf, 2010, pp. 12–14). The intention is to shed light on the decisions and negotiation processes that underlie the emergence of concrete translations and condition their specific features. A further issue concerns the social structures or higher-level contexts of action in which practices of translation are embedded and how they in turn influence these structures. Another topic of research is how macro- and micro-contexts intermesh in interpreter-mediated situations (Inghilleri, 2003). Researchers are interested in what can be said in sociological terms about the significance of translations and interpreted renderings, and hence also of translators, and what conclusions can be drawn from the quantity and constituents of translation flows between different cultures concerning the relative prestige enjoyed by languages, which are likewise treated as actors (Bachleitner & Wolf, 2010). Here,

the examination of translation flows appears to offer an excellent approach to analyzing the international(ized) market in cultural or symbolic goods, where the relevant studies draw, with various degrees of theoretical sophistication, on the concepts of Bourdieu (see the articles in Heilbron & Sapiró, 2002, 2008; Casanova, 2004). Besides these approaches, studies within the sociology of the professions have been devoted to issues of professionalization and the status of translators as a professional group. In an attempt to systematize the contributions to date, Wolf distinguishes between a “sociology of the agents,” a “sociology of the process,” and a “sociology of the product,” which reveals the main lines of research, though of course overlaps occur (Wolf, 2007a; Chesterman, 2006). Sociological concepts have also demonstrated their potential in an ethics of translation (Gouanvic, 2007a, pp. 41–9) and an ethics of the translator (Inghilleri, 2008).

Initial distinctions concerning the actors involved in the process of translation and the various associated roles, which have remained relevant for subsequent sociological examinations, were made by Holz-Mänttari in the 1980s in a contribution which took its orientation from the theory of action and retained a strong emphasis on the cooperative aspects (though without thematizing potential associated problems; see Wolf, 1999). The conceptualization of translation as a norm-regulated process within the context of a descriptive approach that considers translations as facts of the relevant target culture (descriptive translation studies)—Gideon Toury being a prominent exponent—also laid important foundations for a sociological approach. The conception of “translation as institution” (Hermans, 1996) led to a differentiation concerning the degree of obligatoriness of norms, where this property of norms does not arise *ex nihilo* or from abstract entities, such as culture or society, but from the power of interpretation and implementation of the actors and institutions standing behind them (see also Hermans, 1998). The focus of analysis, therefore, is social realities. Hermans (1996) conceives of norms, following Luhmann, as simultaneously cognitive and normative expectations which do not exhibit first and foremost the character of rules or constraints but are primarily geared to reducing behavioral uncertainty and enabling cooperation (see the problem of double contingency in Luhmann, 1984).

Since the 1990s sociological approaches to translation have been enriched by integrating the problems and methods of three theorists in particular, first Pierre Bourdieu and Niklas Luhmann, and later also Bruno Latour. These approaches now make important findings available in turn to other disciplines, thus raising the prospect of a convergence among them.

Pierre Bourdieu’s *theory of practice as practice* (see Bourdieu, 2003/1997) represents a theory of action which transcends conventional antinomies between “agency” and “structure,” between subjectivity and objectivity, and between internal and external explanatory factors (see Bourdieu, 2000/1972). As such it has played a major role in consolidating sociological approaches to translation in theoretical and methodological respects, in addition to spurring a large number of case studies. In Bourdieu’s strictly relational conception, which is diametrically opposed to substantialist ones, the conditions of possibility of actions depend on the interplay between *field* and *habitus* (Bourdieu also speaks of “silent complicity” between *field* and *habitus*). With his concept of *fields*, Bourdieu, like Luhmann, pursues a theoretical approach seeking to explain differentiation (on the differences and commonalities see Kneer, 2004). According to Bourdieu, *fields* are governed by at least four central principles: They constitute themselves through protracted, and to a certain extent reversible, processes of autonomization; they are hierarchically structured; they are marked by permanent internal struggles to preserve or change positions within the *field*; and they reproduce themselves through these same struggles. Examples of *fields* are the literary, scientific, political, religious, economic, and juridical. Each *field* has its own *illusio* (not to be confused with “illusion”), a set of beliefs to which those participating in the *field* adhere,

which those entering the *field* adopt, and which are not reducible to those prevailing in other *fields*. Likewise each *field* exhibits a specific distribution of the different kinds of *capital*, be it economic, cultural, social, or symbolic.

Theorists who defend a Bourdieuan approach to translation as a social practice question, in part for different reasons, whether it is appropriate to speak in terms of a “translation field.” In support they argue that the preconditions for the existence of an autonomous “translation field” outlined above are not met, because in this case there is too much instability, the social relations geared to translation are not durable, and the struggle for positions is not sufficiently pronounced (Wolf, 2007b). Furthermore there are doubts concerning the degree of autonomy from other *fields*, which feature as clients (Gouanvic, 2007b, p. 81).

Habitus is a generative principle comprising schemes of perception, of thinking, and of acting which are simultaneously social and cognitive modes of di-vision (i.e., vision and division) of the world. The incorporation of a “primary habitus” begins virtually with the first breath the agent takes, whereas the agent develops a “secondary habitus” upon entering a specialized *field*. When applied to translation studies the concept of *habitus* as simultaneously structured and structuring makes it possible to account for the social trajectories of translators in a very illuminating manner. Taken together, these concepts provide translation studies with analytical instruments that can serve as a corrective to the concepts of norms, rules, laws, strategies, and idiosyncrasies, which seem to be located either too much on the side of society or culture or too much on the side of the individual. Whereas the peculiar explanatory power of the concept resides primarily in the unquestioned pre-stabilization achieved by the *habitus*, it also makes it possible to analyze how cleavages between *habitus* and *field* can arise. The latter is shown by a study on the discomforting topic of the demeanor of military linguists in Guantánamo and the ethical conflicts they experienced (Inghilleri, 2008).

Gouanvic has demonstrated convincingly how the “importation” of whole subfields (he uses examples of the importation of science fiction and realist novels from the USA to France; see Gouanvic, 1999, 2007a) is brought about not by needs or gaps in the target culture but by *homologies* between the cultures concerned. He goes so far as to understand *illusio* in terms of tendencies of cultural superimposition in the process of globalization (Gouanvic, 2007b, p. 90), so that we would have at our disposal a threefold analytical instrument: the *illusio* of single texts, the *illusio* of genres, and the *illusio* of literature per se. Besides the central analytical instruments of Bourdieu outlined above, his approach allows for consideration of phenomena such as the “consecration mechanisms” conducive to the evolution of new subfields or the enhancement of one’s status through the accumulation of *symbolic capital*.

In contrast to the selective reception of Pierre Bourdieu’s oeuvre within a variety of disciplines and national contexts, in translation studies he is perceived as a sociologist as well as an ethnographer, though perhaps to a lesser extent as a philosopher. The critical potential of his approach began to make itself felt in translation studies because scholars working within this strand of translation sociology were highly receptive to these different aspects of Bourdieu’s work.

Actor-network theory (ANT) was developed in the context of science studies by Bruno Latour and his colleagues (Latour, 2005). One of its essential features is its focus on not treating “the social” as an attribute. The productive “disconcertment” which this entails begins already with the definition of what constitutes a social group. According to Latour, there are no preexisting social groups which can readily serve as units of analysis. In this context we can only speak of *group formation* (2005, p. 29). Moreover, the sociologist depends on these processes of group formation for her research—while being implicated in them herself—because they leave traces which are the only material accessible to her.

Actions on this conception are not produced by actors; rather the latter are moved to act. However, it would be a misconception and reductive to invoke “power” or “social forces” as underlying motives and the ultimate explanation (2005, pp. 82–3). Not only persons can serve as actors for Latour; nonhumans and (hybrid) objects also possess “agency” in the relevant sense. The ability to induce action is captured by the notion of *translation*, which in this approach does not simply proceed smoothly but always involves a corresponding effort. Thus *translation* is something entirely different from mere diffusion, transportation, or transmission (Latour, 2005, pp. 106, 108). The *networks* that result from such sequences of *translations* have a conceptual status and it would be a complete—and all too common—misunderstanding to treat them as something concrete, even palpable, on an analogy with social or technical networks or to associate them with the activity of “networking” in organizations or its results (2005, pp. 128–33). On the whole it is not only preferable but indispensable for every research project to concentrate on the process and—to cite a formulation ceaselessly employed by Latour—“to follow the actors” in a meticulous way. Taking ANT as her point of departure, the sociologist cannot settle questions of scale—that is, whether a sociological study concerns the micro-, meso-, or macro-level—in advance but can answer them only in the context of ongoing research itself. These aspects find tangible expression in a study by Buzelin (2007) of “translations in the making,” as exemplified by three translation projects in three independent publishing houses in Québec. Her approach proves to be highly productive, especially in the context of increasing globalization in the publishing industry. It also seems to be in accord with Latour’s cautionary note that research within ANT must take into consideration the peculiarities of the case at hand (Latour, 2005, p. 130). Buzelin concludes that it would be timely to recognize the extent to which translation is the result of processes of co-editing and of co-translation in which far more actors exercise influence than is commonly assumed, something which can be confirmed only with the kind of ethnographic accuracy provided by an ANT study (Buzelin, 2007). It is interesting to note that, whereas translation scholars who take their lead from Bourdieu for the most part do not assume the existence of an autonomous field of translation, among other things because of the instability of relations resulting from translational exchange (see above), Buzelin is forced to conclude that her findings—that is, the patterns observed—exhibit an unexpectedly high level of stability (2007, p. 165). She follows Latour in concluding that the main contribution of ANT to translation studies resides in providing a remedy for the criticism of Bourdieu that he supposedly neglects concrete contents (of works of art, scientific findings, etc.; see Latour 2005, pp. 234–7), while at the same time enhancing the ability to account for unpredictability and creativity (Buzelin, 2005). Instead of adopting a retrospective view, embracing ANT means studying processes while they are ongoing, while their outcomes are still uncertain and there is still risk of failure. All in all, Latour elevates the status of exhaustive descriptions above something which is often discredited as “mere description” lacking in explanatory power (Latour, 2005, p. 150; see also p. 137). As far as points of convergence and divergence between the theories of Bourdieu and Latour are concerned, Buzelin is convinced that the two theories may be mutually enriching (Buzelin, 2005; for discussions of other network theories in relation to translation see Buzelin & Folaron, 2007).

The theory of social systems (SST) of Niklas Luhmann (1984) is concerned with the functional differentiation of society into *systems* (e.g., the political, juridical, economic, religious, cultural, etc., systems) and their *environments* (i.e., everything outside the system in question). “Functional” here should not be understood in the sense of fulfilling a function with respect to some higher-level entity of whatever kind. *Systems* consist (exclusively) of *communications* regulated by *binary codes* which are peculiar to the corresponding system, and it alone, and are concretized in so-called *programs*. Because *psychic systems* have their own medium, namely consciousness, they are relegated to the *environment*, with the result

that systems theory dispenses with persons or individuals as actors. *Systems* can react only to *communications* within their own *codes* (e.g., new/old for the cultural system or true/false for the scientific system). *Systems* are characterized by *autopoiesis*, that is, the ability to perpetuate themselves, and they exhibit *operational closure*, so that autonomy—in contrast to Bourdieu's theory (see Kneer, 2004)—is not a matter of degree, but is a fundamental feature of *systems*. This is not to say that the systems in question do not involve any interactions or contacts whatsoever with other systems (in their status as *environment*). These come about by way of (*inter-*)*penetration* (see Luhmann, 1984, pp. 289–96), *irritations*, and *perturbations*, which are not only unavoidable but necessary and can eventually bring about changes in the *system*, though they are always mediated by the system-specific codes.

That translation can also be conceived in systemic terms and hence as self-referential—*communications* producing *communications*—is due to the fact that there is never a final, irrevocable translation (otherwise it would cease to be a translation), but only temporarily valid versions open to contestation (Hermans, 2007). Interpreting translation in terms of Luhmannian systems theory leaves open at what level translation should be situated. Here the theory presents a range of interpretive options. Rereading previous texts in translation studies not necessarily formulated in terms of systems theory, Tyulenev maintains that translation can be regarded, and has been regarded, either as itself a system (see Hermans, 1999, 2007), as a “subsystem”, or as a “boundary phenomenon” regulating the opening vs. closing between *system* and *environment* (see Tyulenev, 2009).

It is impossible to overstate the importance of the contribution of the sociology of translation to the self-reflection of the discipline. This can lead, among other things, to a Bourdieuan socio-analysis of translation scholars which relates their attitudes to the respective positions in the scientific field from which they formulate their theories. It could also take the form of including the discipline itself within the field of observation, following systems theory. Whereas during the initial phase of development of sociological approaches it may have been indispensable to concentrate on just a few conceptual frameworks, this may give way in the not too distant future to an increasing diversification of approaches.

Solan, Lawrence M.

NICCI MACLEOD

Lawrence M. Solan (1952–) is Don Forchelli Professor of Law at Brooklyn Law School, and well known for his contributions to the field of language and law with his books *The Language of Judges* (1993) and *Speaking of Crime: The Language of Criminal Justice* with Peter Tiersma (Solan & Tiersma, 2005), as well as numerous scholarly articles. Prior to joining Brooklyn Law School in 1996, Solan was a partner in the firm of Orans, Elsen, and Lupert, where he specialized in complex civil litigation. Before that, he served as law clerk to Justice Stewart Pollock of the Supreme Court of New Jersey. He served as president of the International Association of Forensic Linguistics from 1999 to 2003, and is on the editorial board of *The International Journal of Speech, Language and the Law*. His publications within the field of language and law have been concerned with the interpretation of written legal texts such as contracts and statutes (Solan, 2004), admissibility in US courts of linguists' testimony in general (Solan & Tiersma, 2004) and more specifically as "semantic tour-guides" in cases of disputed interpretation of legal documents (Solan, 1998).

After completing his PhD in linguistics at the University of Massachusetts in 1978, Solan attended Harvard Law School, during which time he took a summer job at the Manhattan law firm Phillips Nizer. It was here that his interest in the interface between language and the law was first aroused. Representing a chemical company in dispute with its insurance company over the latter's refusal to pay out proceeds following some severe environmental damage, he found himself concerned with the language of the insurance policy. With the realization that many of the disputes had arisen as a result of choices over punctuation and syntax, the two areas of expertise became united. Solan started collecting examples of judges' discussion of language, which subsequently formed the basis of his 1993 book, the result of his investigations into those occasions when disputes over meaning in legal documents arise and "judges act as linguists" (Solan, 1993, p. xi). The examples he presents demonstrate that judges' linguistic descriptions are inconsistent, and often incoherent and idiosyncratic. He puts forward two explanations for this: first, the pressure on judges to legitimize their power by speaking with an authoritative voice and second, the necessity of giving the appearance of adhering to the rule of law. "Judges do not make good linguists," he claims, "because they are using linguistic principles to accomplish an agenda distinct from the principles about which they write" (Solan, 1993, p. 62). Solan discusses several linguistic phenomena which have resulted in conflicting interpretations of legal documents, including referential ambiguity arising from the use of pronouns, which he describes as "semantically degenerate . . . they do not contain enough on their own to name the individual to which they are intended to refer . . . a natural source of uncertainty" (Solan, 1993, p. 38). He moves on to discussing lawyers' pursuit of precision in drafting legal documents, noting that it has given rise to the gradual development of a special, "superprecise" syntax. He discusses the ongoing tension between precision and comprehensibility, concluding that while legal professionals could "engage in an all out effort to write more clearly, with fewer unnecessarily legalistic expressions," doing so would "never be sufficient to make natural language any more precise than our cognitive capacities permit" (Solan, 1993, p. 138).

Another area in which Solan has published widely is the admissibility of linguists' testimony in US courts (Solan, 1998; Tiersma & Solan, 2002, 2004; Solan & Tiersma, 2004).

Courts in the USA have allowed linguists to testify on such issues as the probable origin of a speaker, the comprehensibility of a text, whether a particular defendant understood the Miranda warning, and the phonetic similarity of two competing trademarks. When the issue at hand is the interpretation of legal texts, however, the admissibility of linguistic testimony has been more controversial. Reasons for judicial reluctance to admit linguistic expertise in these matters include concerns that it is not sufficiently reliable, the sense that it is up to judges, not linguists, to decide meaning as a matter of law, and the belief that meaning can just as well be decided by a jury (Solan, 1998). In his 1998 article Solan explores this last issue in depth, acknowledging that while a jury's intuitions are sufficient for matters of interpretation when the crucial statements or discourses are short and straightforward, in those cases where a linguistics expert is able to increase a juror's confidence "by converting . . . an intuitive sympathy into a structured understanding" (Solan, 1998, p. 94), their services can be of assistance. The linguist, he postulates, can assist judges and juries in evaluating linguistic issues fully, acting as a "semantic tour guide." The role of the linguist in these situations is not, Solan claims, to give his or her expert opinion on the meaning of a text, but to explain the *basis* of possible meanings, and to point out alternative interpretations. Thus, while judges may sometimes be quite justified in prohibiting unhelpful expert testimony, "if a jury is forthrightly told about the scope of a linguist's expertise, there is no reason why the system should not benefit from this knowledge" (Solan, 1998, p. 96). More careful consideration of the potential benefits of expert linguists' assistance, he concludes, "can ultimately serve to enhance the status of linguistics as a useful tool in legal analysis" (Solan, 1998, p. 102).

Solan and Tiersma's (2005) book presents a comprehensive review of the many areas around the intersection of language and law, paying particular attention to the relevance of pragmatic theory to criminal procedure, the provision of language-based evidence, and crimes—such as bribery, threats, and perjury—that are committed *by means of* language. It therefore provides a detailed exploration of the ways in which linguistics and related fields can provide a better understanding of the workings of the US legal system—and consequently, provide tools with which to address the problems therein. At the time of writing, Solan's book on the interpretation of statutes, *The Language of Statutes: Laws and Their Interpretation* was published in 2010, and *The Oxford Handbook of Language and Law*, coedited with Peter Tiersma, was published in 2012.

Sound and Spelling

BENEDETTA BASSETTI

Spelling means representing a language in writing by using the letters of an alphabet according to conventions. This entry will first describe the principles by which spelling represents sound and review differences in phonological transparency among alphabetic writing systems. It will then overview the consequences of the sound–spelling relationship for reading, spelling, literacy acquisition, metalinguistic awareness, pronunciation, and linguistic descriptions of spoken language.

The Representation of Sound in Alphabetic Writing Systems

Unlike other types of writing systems that represent syllables, consonants, or other language units, an *alphabetic writing system* represents each phoneme of a spoken language with one symbol. It is therefore a *phonographic system* (it represents the sounds of the spoken language), and in particular a *phonemic system* (it represents phonemes; for an overview, see Coulmas, 2003). Alphabetic writing systems are written with *scripts* (sets of written symbols) called *alphabets*, whose smallest units are called *letters*. Although there are just a few alphabetic scripts, many languages are written with an alphabet. The most widely used one is the Roman alphabet, other often-cited examples are Greek and Cyrillic, and less well-known ones include the Armenian and Georgian alphabets. Writing a language using letters is called *spelling* (although the term can also be used for nonalphabetic writing systems).

Alphabetic writing systems work on the principle of segmenting spoken language into phonemes and representing each phoneme with a grapheme, for instance representing the English word /kæʃ/ with <cash> (the symbols “< >” denote an orthographic form). A *grapheme* is the smallest identifiable unit in a writing system (see Coulmas, 1999). In an alphabetic writing system, a grapheme can be a letter or a letter combination. For instance, in English the grapheme consists of one letter and represents the phoneme /b/, the grapheme <sh> is a digraph (combination of two letters) and represents the phoneme /ʃ/. Since in English there are more phonemes (e.g., 44 in British English Received Pronunciation) than letters (26), it is not possible to represent all phonemes by means of a single letter. The higher number of phonemes compared with letters can explain why /θ/ is represented by the digraph <th>, and why <th> represents both /θ/ and /ð/.

The correspondences between graphemes and phonemes in alphabetic writing systems are called *grapheme–phoneme correspondences* (GPC, also “grapheme–phoneme conversion rules”), and in the opposite direction the correspondences between phonemes and graphemes are called *phoneme–grapheme correspondences* (PGC) (see Coulmas, 2003). For instance, in English the grapheme <d> corresponds to the phoneme /d/, and the phoneme /ʃ/ to the grapheme <sh>. Correspondences are specific to each writing system. For instance, in both the English and Italian writing systems the grapheme corresponds to /b/, but whereas the grapheme <ch> corresponds to /k/ in Italian, in English it corresponds to /k/ (in *chaos*), /ʃ/ (in *machine*), and /tʃ/ (in *child*). Therefore, the same orthographic word <china> is pronounced /kina/ in Italian and /ˈtʃɪnə/ in English.

Phonological Transparency

In an ideal alphabetic writing system, the same phoneme should always be spelled with the same grapheme and the same grapheme should always be pronounced with the same phoneme. This is the *alphabetic principle*. No writing system follows this principle entirely, but different writing systems are more or less close to it.

Different writing systems then have different levels of *phonological transparency*, and are described as more “transparent” or “opaque.” This has also been called *orthographic depth*, and different writing systems have been described as “deeper” or “shallower” (e.g., Katz & Frost, 1992). Examples of phonologically transparent alphabetic writing systems include Finnish, German, and Spanish, while French is an example of an opaque one (for descriptions of various writing systems, see Daniels & Bright, 1996; Coulmas, 1999; Joshi & Aaron, 2006). Italian and English are often cited as examples of writing systems at the opposite ends of this phonologically transparency continuum, and will be used as examples in this entry. In transparent writing systems such as Italian there are mostly (but not only) one-to-one correspondences between graphemes and phonemes and between phonemes and graphemes. For instance, in Italian <a> is always pronounced /a/ and is always pronounced /b/; in the opposite direction, /a/ is always spelled <a> and /b/ is always spelled . In English, the grapheme <a> can represent many phonemes (e.g., /æ/ in *cat*, /ɛ/ in *many*, /ɔ:/ in *call*, /ɑ:/ in *father*), and can represent /b/ or be silent (as in *debt*); in the opposite direction, /b/ can be spelled or <bb>. Some English graphemes correspond to high numbers of phonemes, for instance even the relatively rare grapheme <gh> can correspond to /g/ (in *ghost*) or /f/ (in *enough*), be silent (as in *high*), or even correspond to /p/ (as in *hiccough*) and /ə/ (as in *Edinburgh*). In English there are then one-to-many grapheme–phoneme correspondences, and one-to-many phoneme–grapheme correspondences; furthermore, correspondences for vowels are more complex than for consonants, due to the large number of vowels and the small number of vowel letters (see Carney, 1994, for British English correspondences, and Venezky, 1999, for American English ones). The degree of transparency is not the same across directions, whether grapheme-to-phoneme or phoneme-to-grapheme, and in various writing systems GPCs are more transparent than PGCs (e.g., see Harris & Giannuoli, 1999, for Greek). There is currently no agreement on how to calculate degrees of phonological transparency, although various proposals have been put forward, for instance calculating the phoneme-to-grapheme ratio (Coulmas, 2003).

Beyond the Alphabetic Principle: The Case of English Spelling

English is often presented as a clear example of a phonologically opaque alphabetic writing system, but its low level of phonological transparency is partly due to a higher level of morphemic transparency than other writing systems.

The low level of transparency of written English has several causes. It is partly due to historical reasons, because the spoken language evolved but the spelling of words remained fixed (for a history of written English, see Scragg, 1974). For instance, the <k> in <know>, which is silent in contemporary English, was pronounced in Old English, and it therefore represents a phonemic transcription of an earlier spoken word. Another reason is that foreign words were introduced from languages that had different grapheme–phoneme correspondences, so in English the same grapheme <c> is pronounced /k/ or /s/ in words of French origin (*‘cab,’* from *cabriolet*; *‘cede,’* from *céder*) and /tʃ/ in words of Italian origin (*‘cello,’* from *violoncello*). English GPCs can then derive from those of classical languages, Romance languages, and other languages.

Another reason why English is phonologically opaque is because it is more morphologically transparent, and phonological transparency is sacrificed in order to maintain morphological transparency. For instance, the past tense morpheme is pronounced /t/, /d/, or /ɪd/ depending on the phonological context, but it is always spelled <ed>. In a fully alphabetic writing system there would be three different spellings, for instance <t>, <d>, and <ed>. Also, in English /saɪn/ is spelled as <sign> with a <g> to show its common morpheme with <signature> regardless of the pronunciation. The Italian writing system instead represents the sound of words regardless of their morphology, spelling <segno> with <e> and <significato> with <i> to represent the spoken forms /'seɲ:ɒ/ and /sɪɲ:ifi'kato/, whereas a morphologically transparent representation could for instance be <signo> with an <i>. English can therefore be placed lower than Italian on the phonological transparency continuum, but higher on the morphological transparency continuum.

Some of the irregular correspondences between sounds and spellings in English are then due to the fact that the writing system does not only aim at representing sound. Although having different written forms for the same phonological form creates difficulty for spelling, it can facilitate reading, for instance with homophone disambiguation, as when in English /raɪt/ is spelled as <right>, <write>, or <rite>, or content words such as *inn* and *bee* are spelled with three letters but function words such as *in* and *be* are spelled with two letters (Cook, 2004). Such spellings may confuse writers but may facilitate readers. Still, despite the advantages of a morphemically transparent writing system, there is a commonly held view that the best alphabetic writing system is a phonologically transparent one. For this reason, there have been various proposals for spelling reforms to bring spelling closer to sound, from Noah Webster's American spelling to the proposals of the English Spelling Society in the United Kingdom, or for simpler spelling systems to be used with children, such as the Initial Teaching Alphabet, which have enjoyed varying degrees of success (for an overview, see Sampson, 1985).

Consequences of the Relationship Between Sound and Spelling

The level of phonological transparency of a writing system affects reading and spelling processes, literacy acquisition, and even literate speakers' metalinguistic awareness and pronunciation. For instance, children learn more phonologically transparent writing systems faster than more opaque ones, so that literacy acquisition is faster in Greek and Italian children than in English-speaking children (Elley, 1994), and the latter struggle particularly in reading pseudowords, that is, nonexistent words that can be pronounced using grapheme–phoneme correspondence rules (Seymour, Aro, & Erskine, 2003). Phonemic awareness, that is, the ability to identify and manipulate phonemes, also develops earlier in children who acquire literacy in more transparent alphabetic writing systems (Spencer & Hanley, 2003). Compared with readers of more phonologically transparent writing systems, readers of more opaque writing systems rely more on the whole-word strategy and less on grapheme–phoneme decoding (Frost, Katz, & Bentin, 1987); they need to decode longer orthographic units such as onsets, rimes, and syllables (the “psycholinguistic grain size theory,” Goswami, Ziegler, Dalton, & Schneider, 2003); and they need to rely more on analogy for reading words (Gombert, Bryant, & Warrick, 1997). Dyslexia may be more widespread among users of more phonologically opaque alphabetic writing systems (Smythe, Everatt, & Salter, 2003), and dyslexic users of such writing systems may display more severe difficulties (Paulesu et al., 2001). Second language learners are often influenced by the relative levels of phonological transparency of their first and second language writing systems in their reading and spelling processes and second language phonemic awareness (Cook & Bassetti, 2005), and the spelling of second language words can even affect second language learners' pronunciation (Bassetti, 2008).

Finally, another important issue is whether the relationship of sound and spelling affects the development of linguistic theories. Spelling provides a permanent visual representation of language, which is likely to affect people's ideas about their spoken language. Nonlinguists are affected by the orthographic representations of sound when performing metalinguistic awareness tasks, such as counting or manipulating phonemes in spoken words, so that literate English speakers count more phonemes in a word that is spelled with more letters (e.g., <pitch> vs. <rich>, Derwing, 1992). Such effects of orthography on phonemic awareness appear in children concurrently with literacy, when for instance children start considering nasal consonants as separate phonemes (Treiman, Zukowski, & Richmond-Welty, 1995) and counting more phonemes in words spelled with more letters (Ehri & Wilce, 1980). In some cases, word pronunciations have changed due to their spellings: *spelling pronunciations* happen when people pronounce a word by using grapheme-phoneme correspondences to sound out the word's written form, and such pronunciations can then become standard. This is why *author* is pronounced with a /θ/ rather than its original pronunciation with a /t/ (Bloomfield, 1927). Some scholars have then even argued that linguists' analyses of the spoken language might also be influenced by the characteristics of their writing systems. For instance, it has been suggested that the concept of phoneme only emerged because Western linguists were literate in alphabetic writing systems (Linell, 2005), and that the phoneme was originally conceived as the unit that would be represented by a grapheme in an ideal writing system (see Sampson, 1985).

Conclusion

In conclusion, the relationship between sound and spelling is more complex than saying that spelling represents sound, as different alphabetic writing systems vary in their position along the phonological and morphological transparency continua. The complex relationship between sound and spelling affects reading, spelling, literacy acquisition, metalinguistic awareness, pronunciation, and possibly linguistic descriptions of spoken language.

Spada, Nina

PATSY M. LIGHTBOWN

Nina Spada (1953–) is internationally known for her classroom-centered research on second language learning and teaching. In scores of publications she has reported on descriptive and experimental studies designed to characterize the interaction between teachers and students and to discover the features of this interaction that are most effective in promoting second language development.

Spada received her BA from the University of British Columbia in 1975. She taught ESL (English as a second language) to adult learners in Vancouver before moving to Montreal to pursue her MA at Concordia University. At Concordia, she continued teaching and also worked on curriculum development for students in pre-university ESL courses. Among her colleagues at Concordia was Michael Long, whose work on interaction in SLA (second language acquisition) was influential in her later work in classroom observation. In her MA research she investigated the influence of out-of-school contact with English on the second language learning of young Francophone learners in Quebec schools, where, at the time, classroom teaching was typically limited to an audio-lingual approach. The study was carried out in the broader context of a research project directed by Patsy M. Lightbown, who was to become her colleague and coresearcher on many studies of classroom SLA.

In 1979–80, Spada was among the first international scholars teaching in the People's Republic of China. At the Guangzhou Institute of Foreign Languages (now Guangdong University of Foreign Studies) she worked with Chinese and Canadian colleagues to develop communicative language teaching approaches and materials that were compatible with the needs and resources of Chinese institutions for training English-language teachers.

On her return from China, Spada enrolled in a PhD program at the Ontario Institute for Studies in Education at the University of Toronto. During her studies there, she was involved in the Development of Bilingual Proficiency project where she collaborated with Patrick Allen and Maria Fröhlich in creating a scheme for observing and analyzing classroom interaction. The scheme, called COLT (Communicative Orientation of Language Teaching), proved to be an effective tool for assessing characteristics associated with communicative language teaching. COLT has been used in classroom-based research around the world. In 1995 Spada and Fröhlich published a book that provided scholars with a detailed explanation of COLT categories and coding procedures, as well as examples of some of the many research projects in which it had been used in Australia, Canada, Greece, Japan, and Spain.

Spada's doctoral research extended her MA thesis by exploring the interactions between type of instruction and out-of-class second language use on the L2 development of adult classroom learners of ESL. Because students in her study were exposed to instruction that differed in terms of its communicative orientation (assessed through the use of COLT), she was able to show that instructional characteristics can have different effectiveness according to how and how much students use the language outside the classroom.

On completion of her PhD, Spada went to the University of Michigan, where she further developed her research interests with colleagues including Susan Gass and Virginia Samuda. In 1985, she returned to Canada to take up a position at McGill University where she would remain for 15 years. In collaboration with other researchers at McGill and Concordia,

including Patsy M. Lightbown, Lydia White, and Roy Lyster, she produced dozens of publications and conference presentations, many of them based on research in experimental “intensive” ESL programs in Quebec primary schools. Using COLT in both observational and experimental studies, the research team was able to identify instructional characteristics that were related to successful learning. These studies produced substantial evidence for the effectiveness of classroom interaction that focused primarily on meaning but also included form-focused teaching. In 1997, she published a much-cited state-of-the-art paper on form-focused instruction in the journal *Language Teaching*. At McGill, Spada supervised the doctoral studies of scholars who are now teaching at universities in Canada and the United Kingdom. In addition, she served as a member of doctoral committees for students in second language education, linguistics, and educational psychology.

In 2000, Spada took up a professorship at the University of Toronto. In this post, she has continued to carry out research on classroom teaching and learning. Among the research projects she has led at the University of Toronto is an investigation contrasting form-focused instruction that is integrated into meaning-focused activities with form-focused instruction that is provided separately from meaning-focused activities. The research has included studies of students’ and teachers’ attitudes toward these two types of instruction, explored through the use of questionnaires that are administered both before and after the participants engage in instructional activities that exemplify the two approaches. In this context, Spada has mentored many graduate students in the research process and supervised the thesis research of numerous MA and PhD students. In keeping with her commitment to classroom teaching, she also teaches courses for undergraduate students in teacher training programs.

Spada’s service to the profession includes several years as a member of the board of the American Association for Applied Linguistics, followed by terms as Vice President and conference organizer and then as President and Past President. She has been an invited professor or speaker throughout Canada as well as in Europe, Latin America, Asia, Australia, the United States, and the United Kingdom. As a reviewer/evaluator or editorial board member, she has contributed to the work of virtually every major journal publishing research in second language acquisition. For John Benjamins, she coedits the *Language Learning and Language Teaching* series, in which she has edited more than a dozen books by high-profile researchers.

Articles based on Spada’s research have appeared in *SSLA*, *Applied Linguistics*, *TESOL Quarterly*, *Language Learning*, *TESL Canada Journal*, *Language and Education*, *Canadian Modern Language Review*, and other professional journals and edited books. She is coauthor (with Patsy M. Lightbown) of *How Languages Are Learned*, first published in 1993. The third edition was published by Oxford University Press in 2006 and is a foundation text in many applied linguistics and teacher education programs. Spada’s publications, presentations, and teaching have provided scholars, teachers, and students with valuable insights into how instruction affects second language learning in different environments.

Spanish for Specific Purposes

LOURDES SÁNCHEZ-LÓPEZ

Introduction

This entry provides a general description and an overview of Spanish for specific purposes (SSP) as an emerging subdiscipline within the languages for specific purposes (LSP) framework. To understand the teaching and learning of SSP today we need to take a look at the history of LSP. The teaching of LSP originated in the 1960s in the United Kingdom and was established as a discipline as English for specific purposes (ESP). A landmark publication, *The Linguistic Sciences and Language Teaching* (Halliday, Strevens, & McIntosh, 1964), called for linguists to carry out research based on samples of language in specific contexts to develop appropriate pedagogical materials. The focus of LSP had as its primary goal to fulfill the communicative needs of a specific group of people (Hutchinson & Waters, 1987). Since the 1960s, slow but steady global attention has been given to LSP in both research and the development of pedagogical materials for the classroom for the professions, such as business, law, medicine, sciences, social work, translation, and interpretation, among others.

Background

Even though ESP has had a definite place in education and research globally for decades, it is only since the 1980s that SSP has been part of the academy, especially in Europe and the United States, and more recently in some parts of Latin America. The growing immigration flows of Spanish-speaking people from all parts of Latin America to the United States and Europe have impacted educational and professional settings on both sides of the Atlantic leading to an urgent need for Spanish for specific contexts.

In the United States Spanish is the most widely taught language at all levels of education and the second language of the country, with almost 49 million Spanish speakers in 2009 and a projected Hispanic population of 132.8 million (30% of the total population) by the year 2050 (US Census Bureau, 2010). In Europe, Spanish is the second most common foreign language taught after English, and the Spanish-speaking population is growing due to immigration from many Latin American countries. For example, the 2010 Spanish census shows that 40% of the total immigrant population comes from Latin America (Instituto Nacional de Estadística, 2011). As the overall number of first language Spanish speakers in the world, estimated at 329 million (Lewis, 2009), keeps increasing, Spanish has a prominent place in many countries, especially in academic and professional contexts.

In direct relation to the growth of Spanish as a world language, recent data suggest an urgent need to revise foreign-language curricula to meet the needs of students and society better (Modern Language Association, 2007, 2009). As Doyle, an SSP pioneer (2010) claims:

In addition to language acquisition and the traditional study of literature, civilization and culture, and linguistics, how do we enhance the preparation of today's students of Spanish for fuller participation in the global village and economy into which they will graduate? How might they become better prepared to put their study of other languages and culture

2 SPANISH FOR SPECIFIC PURPOSES

to use, which increasingly factors in their real world needs and inclinations, once they begin to seek gainful employment? (p. 80)

Many university programs internationally have been responsive to these new needs and have adapted (or are in the process of adapting) their existing Spanish programs or have developed new programs to respond to these emerging trends (Sánchez-López, 2010; Doyle, 2010). As ESP has been well established worldwide for decades, now SSP is also being recognized as a focus of study in higher education. In the early 1990s in the United States, Europe, and Latin America many new course offerings in SSP (business, medical, and legal Spanish, Spanish for teachers, and translation and interpretation, among others) began as parts of mainstream language programs. As an outgrowth from this movement, completely new specialized freestanding programs, such as minors, certificates, majors, or graduate degrees, emerged in these areas (see Sánchez-López, 2010 for a selection of SSP programs). As a consequence, there has been a corresponding proliferation of textbooks, instructional Web sites, professional conferences, workshops, and scholarly papers focusing on SSP.

Three of these initial SSP efforts have become landmark references in the field and deserve to be mentioned. In 1988 the US Department of Education created the Center for International Business Education and Research (CIBER) to promote the country's capacity for international understanding and competitiveness. Today there are 33 CIBERs which serve as regional and national resources to business people, students, and educators. Each CIBER offers activities to advance the study and teaching of international business. Furthermore, in 1998 the American Association of Teachers of Spanish and Portuguese (AATSP) published a volume titled *Spanish and Portuguese for Businesses and the Professions* providing a wealth of expertise in areas such as course and program development and implementation, needs analysis, and cross-cultural communication training (Fryer & Guntermann, 1998). The first part of this work focuses on Spanish and Portuguese for business since Spanish for business was well established before other specific purposes within SSP. The second part presents articles on other professions such as health, law enforcement, social work, translation and interpretation, and science and technology, describing the development of SSP within these contexts and future directions. Today, these areas are also well established within SSP. Another pioneer and now landmark professional resource is the Congreso Internacional de Español para Fines Específicos which held its first meeting in Amsterdam in 2000. Organized by the Spanish Department of Education and the Spanish Embassy in Belgium, the Netherlands, and Luxemburg, the CIEFE gathers international professors and researchers in SSP to discuss current research in the field and future directions. Today the number of SSP professional conferences, workshops, and publications has escalated, although relatively few compared to ESP (see Sánchez-López, 2010, for a selection of pedagogical resources).

Characteristics of Spanish for Specific Purposes

SSP is not considered as a discipline separate from the teaching and learning of Spanish for general purposes, but as an extension (Sánchez-López, 2006). The primary characteristics of SSP are student specificity, needs assessment, communicative precision, real-life and task-based methodology, and instructor flexibility and interest.

Specificity

Similar to ESP, the specificity of SSP programs is not rooted just in the teaching of a specific language (Spanish), nor is it only determined by the specific professional context. The

specificity of SSP depends largely on the students themselves. Generally, courses are geared toward adult learners (both traditional or regular/degree-seeking and nontraditional or nonregular/nondegree-seeking learners), who already have a basic Spanish language background, and who clearly need or will need the language in specific professional or academic contexts (Hutchinson & Waters, 1987; Sánchez-López, 2006).

Needs Assessment

It is for this reason (specificity) that a needs assessment prior to the development of SSP courses or programs is paramount to ensure their quality and success (Lepetit & Cichocki, 2002; Lear, 2006; García-Romeu, 2006). A model needs assessment in an SSP context was done by Lepetit & Cichocki (2002) with pre-health students in South Carolina. The analysis examined the student population, student aspirations, and course content. The students identified three important needs factors: writing and aural skills development, a learning environment that places them in contact with native speakers of Spanish, and the learning of cultural content. These results were pivotal to designing Spanish for health-related professions courses for this state. More recently, Lear (2006) conducted a qualitative case study in a prenatal clinic with a large Hispanic patient population. The study examined the perceptions of the health professionals toward existing “teach-yourself” medical Spanish materials. The results indicate that professionals did not find these materials to be appropriate to their needs. The survey led to the development of pilot syllabi based on more flexibility, a focus on receptive skills, and communicative strategy instruction. Finally, García-Romeu (2006) proposed two different SSP needs assessment tools: a communicative and learning needs survey and a learning outcomes and curriculum negotiation survey. A key characteristic of these tools is that the student is considered the point of departure for the course curriculum development.

Communicative Precision and Knowledge of Sociocultural, Intercultural, and Professional Contexts

Since students need the second language to communicate in specific professional and academic contexts, communication must be precise and there must be a focus on knowledge of the cultural context to promote clear and effective professional exchanges. A key focus is on the reduction of miscommunication and misunderstanding, which could have serious negative implications in many professional situations (Council of Europe, 1996; Llobera, 2000).

Task-Based Instruction and Experiential Learning

To be able to function effectively in academic and professional contexts, people must carry out different tasks required by the specific context. This implies that the use of pragmatic skills is oftentimes more important than grammatical knowledge (Long, 2003). Traditionally, SSP materials have been developed around specific texts. However, SSP materials should be developed around specific tasks to resemble real-life situations as much as possible. Task-based learning helps with the needs assessment processes mentioned earlier. These types of real-life activities are essential in SSP instruction and learning. In addition, SSP curricula typically encompass some type of experiential learning (internship or service-learning course) that gives students the opportunity to practice their linguistic skills in a professional and real-life setting (Felices Lago, 2003; Juan Lázaro, 2003; Long, 2003).

Instructional Flexibility and Professional Interest

SSP instructors must be flexible to be able to: (a) design their course according to the needs assessment results, and (b) constantly adjust their curriculum according to students' needs

and the frequent changes in the professional world. In addition, although SSP instructors do not need to be experts in the target profession, they must have a sincere interest in developing their knowledge in the field in order to connect with students and find the most appropriate instructional resources (Sabater, 2000).

Recent Research in Spanish for Specific Purposes

The four primary areas of SSP studies are business, health professions, law, and translation and interpretation, which are the areas where there is the most immediate need for communication with clients, patients, employees, and other businesses. Therefore, an increasing number of scholarly papers explore these topics, whether it be descriptions of SSP courses or programs, or research studies (Peck, 1987; Mason, 1991, 1992; Held, 1994; Lepetit & Cichocki, 2002; Kalist, 2005; Lear, 2006; Navarro, 2007; Davidson & Long, 2010).

Peck (1987) developed a Spanish course for social workers at UCLA. The main goals were to teach the students to interact more efficiently with Latino clients and carry out tasks in Spanish "in a culturally sensitive manner" (p. 402), and to teach them to develop lifelong language learning techniques. Prior to developing the seven-week course, there was a detailed needs analysis which involved faculty of the School of Social Welfare, administrators from Los Angeles County Department of Children's Services, the Los Angeles County Department of Mental Health, and the United Way. Based on the success of the course, the article provides recommendations for similar courses in other disciplines.

Similarly, Mason (1991) developed an independent study medical Spanish course for pre-med Spanish majors at the University of Virginia. This pilot course illustrated the critical institutional need to offer the course regularly. In addition, it served as a model for subsequent pilot courses with similar characteristics in other areas, such as legal Spanish for pre-law students (Mason, 1992).

Recognizing the new needs and demands of students and the local community, Delgado Community College in the New Orleans area developed a five-year curriculum revision plan to include a series of SSP service courses for allied health professionals, criminal justice professionals, social workers, and business. Different college and local entities were involved in the process. These courses proved popular among students and community members and helped with recruitment and retention (Held, 1994).

Another notable SSP study conducted by Kalist (2005) used data from the National Sample Survey of Registered Nurses 2000. Kalist concluded that bilingual registered nurses (Spanish-English), as opposed to other professions where there are no salary increases offered for proficiency in additional languages, receive wage premiums up to 7% above their annual salary, depending on the number of Spanish speakers in the county of employment. This study offers documentation of economic benefits not only for the SSP field, but also suggests the immediate need for health-related professions programs to add Spanish to their curricula.

Navarro (2007) presented the most relevant aspects of SSP in higher education in Italy after the University Reform. She studied the Spanish course offerings in 30 Italian universities and observed an exponential growth in courses focused on SSP due to new academic requirements and the increasing importance of the Spanish language in the field of international relations.

One of the first pilot SSP courses for medical students was recently developed at the University of Alabama at Birmingham (Davidson & Long, 2010). Due to local increasing demand to communicate with Spanish-speaking patients, a five-day intensive elective course was developed and implemented by UAB faculty for second- and third-year medical students.

Assessment in Spanish for Specific Purposes

Language assessment is an integral part of LSP teaching and learning. Douglas (2000), in his work *Assessing Languages for Specific Purposes*, defines testing languages for specific purposes as

that branch of language testing in which the test content and test methods are derived from an analysis of a specific situation, such as Spanish for Business, Japanese for Tour Guides, Italian for Language Teachers, or English for Air Traffic. (p. 1)

He argues that tests are not general or specific in purpose because all tests are developed with a purpose. However, he maintains that all tests belong to a continuum of specificity from general to specific, and adds that LSP tests fall within communicative language testing, since these should offer the same qualities of good testing practices.

Two of the best known examinations in SSP are the certificate/diploma in Spanish for business, tourism, and health sciences (Diploma, Certificado Superior y Certificado Básico de Español de los Negocios, Turismo y Ciencias de la Salud) from the Madrid Chamber of Commerce and the University of Alcalá, and the “Listening public translation examination” (Spanish), a test developed by the US Federal Bureau of Investigation (FBI) to evaluate whether bilinguals’ language skills are adequate for monitoring conversations in Spanish in contexts of illegal activity, and for writing a summary of the content of such activity.

Another widely recognized tool to assess SSP use is Doyle’s 54-item inventory of testing exercise typology for business Spanish (Doyle, 1998), which can serve as a good model for any SSP instructor. He argued for evaluation as the point of departure in the design of any business Spanish course or program. That is, he felt that the best place to assess needs was to look at learner outcomes and then use those to develop the syllabus and determine what methodology to use for future courses/programs.

Challenges

Even though SSP has come a long way in the last two decades, it still faces critical challenges that need attention. These key challenges are all interconnected and impact one another, and include

1. **Instructors:** Many instructors of Spanish do not feel confident enough to teach (even less develop) SSP courses because they wrongly believe that only “super-instructors” (Sabater, 2000) can do it. As has been discussed earlier, SSP instructors do not need to be experts in the target profession. However, they need to have some knowledge of the target profession to be able to connect with their students, be comfortable around them, and choose appropriate instructional materials.
2. **Recognition:** There is still a lack of professional recognition in higher education for SSP teachers, especially in the United States. Some university departments and administrations still give more importance to traditional fields such as literature or theoretical linguistics when it is time to evaluate for promotion or tenure.
3. **Inadequate funding:** Since there is a lack of professional recognition, some universities do not invest adequately in qualified instructors and professors for SSP courses and programs. Therefore, they often rely on part-time instructors.
4. **Limited pedagogical training:** Although there is a growing body of SSP professional resources such as symposia, conferences, workshops, and publications, formal methodology courses or programs in SSP are not common. Typically, instructors have

- to resort to self-training by adapting their regular methodological knowledge and experience to the new SSP courses.
5. Limited pedagogical resources: Even though there has been a proliferation of SSP pedagogical resources since the 1990s in terms of number of publications, there is still a deficit of high-quality materials based on best practice instruction due to the short history of SSP.

Recommendations and Future Directions

The SSP field clearly has a significant present and an exciting future. As the demand for SSP courses, certificates, and degrees continues to increase worldwide, there must be a parallel proliferation in SSP research to support informed best practice instruction. We urge SSP instructors of all ranks to conduct action research in their classrooms as well as scientific studies to solidify our expanding body of literature, and to improve SSP instructional resources. In addition, SSP-related internships and service learning must become an integral part of SSP course work and of the students' experiential learning component. Institutions of higher education, and in particular languages departments, must give SSP the place that it deserves in terms of recognition and funding. Moreover, teacher education programs must invest in SSP training to avoid, once and for all, the existing self-trained workforce. Finally, the more traditional languages departments worldwide must look at the future proactively by adding SSP to their long-range planning to be able to keep pace with their community and student demands.

Spanish Standardization

MERCEDES NIÑO-MURCIA

A linguistic standard is an abstract model of a given real-life language, proposing to define correct, pure, or genuine usages. Standardization is a work of linguistic engineering, not a natural process. A self-selected group of speakers decides which norms would regulate the correct use of the language. Standardization may or may not ever be put into practice to the same degree among all the language's multiple speech communities. It is an ideal toward which educated speakers gravitate as it becomes a widely publicized marker of social status (Calvet, 1974; Milroy & Milroy, 1985; Joseph, 1987).

In Spanish-speaking communities today, educated speakers are brought up with prescriptions of the Real Academia Española (RAE) ('Royal Spanish Academy'), founded in 1713 in Madrid. It was chartered to be the central institution in defining a canon of correct usage for all the Crown's subjects in domains that then spanned the globe. RAE dictionaries and grammars defined and illustrated "good" language usage. However, in 2007 the RAE and the delegates from the national academies in Spanish-speaking nations approved a grammar more open to pan-Hispanic regional norms.

Historically, we can trace the Spanish standardization process to the 11th century in the then-capital city of Toledo where standardized written production in the vernacular language that later became known as Castilian took normative shape through rules for composing royal documents. The chancery of Alfonso VI (1030–1109) diffused the Carolingian script which other Spanish chanceries adopted. Spelling rules for writing the vernacular added another important aspect to standardization. Alfonso X "the Wise" (1221–84) played an important role in standardizing official written usage.

An equally important agent of standardization was Antonio de Nebrija. His immensely influential *Gramática Castellana* ('Castilian Grammar', 1492/1980) and *Reglas de Orthographia en la Lengua Castellana* ('Spelling Rules in the Castilian Language', 1517/1977) constituted the first grammatical corpus for any neo-Latin language. Nebrija was conscious of the graphophonemic dilemmas that his system would create. In a preface he wrote "But I say that today nobody writes our language purely for lack of some letters: [there are ones that] we pronounce and do not write; and others that on the contrary we write and do not pronounce." After Nebrija, from the 16th through 17th centuries there followed over 20 new Spanish grammars.

When the newly founded Spanish Real Academia de la Lengua Española (RAE) two centuries later wrote upon its coat of arms the slogan *Limpia, fija y da esplendor* ('Cleans, fixes, and lends radiance'), it was proclaiming a mission to protect an already-normativized language from impurities and change, and to enhance its beauty. To these ends the RAE produced as its collective work a *Diccionario de la lengua castellana* also known as *Diccionario de autoridades* (1726–39) because its entries cited desirable usages with quotations from well-known authors and a *Gramática de la lengua castellana* in 1771.

The RAE had undertaken further standardization of Spanish, which at that time still used a variety of spelling norms. Spanish grammarians and philologists, holding diverse and sometimes extreme positions, had already debated spelling for centuries. Every scribe looked for some way to represent problematic sounds inherited from Latin. As early as the sixteenth century, conflict arose between the etymologist or Latinizer (who would maintain graphic Latinisms even if they clashed with the spoken language), and the

2 SPANISH STANDARDIZATION

phonologist, who believed that writing should reflect popular pronunciation. In the 18th century there was still no uniformity.

Although the RAE had begun by recommending etymological orthography, it did not sustain this position for long because diachronic values would give way before demand for answers about current usage and pronunciation, questions to which etymology could not provide adequate solutions. In 1738 the RAE announced a treatise on orthography “que facilitase la escritura en cuanto fuese posible, sin tanta dependencia del origen de las voces” (‘that would make writing as easy as possible, without so much dependence on the origin of words’). The 1741 treatise that was supposed to fulfill this promise paradoxically bears as its title *Orthographía de la lengua castellana*. The *th* and the *ph* prove that etymological standards still had some force. By 1754, the title had been changed to *Ortografía de la lengua castellana*. Nevertheless, it was not until the 19th century, in the fourth edition of the dictionary, and in 1815, in the eighth edition of its *Orthography*, that the words *cristiano*, *sustancia*, *oscuro*, and others were widely written in their now-familiar, un-etymological forms. In spite of the RAE’s efforts, in the 18th century usages remained less than uniform. This situation lasted into the 19th century, when the Crown itself found it necessary to put forward a royal order (April 25, 1844) establishing the teaching of academic orthography. By petition of Queen Isabel II, the RAE published the *Prontuario de ortografía de la lengua castellana* (‘Handbook of Orthography of the Spanish language’, 1857). It was to be adopted by editors in Spain and Paris, and it served to popularize academic spelling in America. It was not until then that academic orthography became widespread in the New World.

These standardizing efforts left out of account, however, the variations which Spanish speech had been acquiring overseas for 300-odd years. The matter of orthographic reforms for Americans was to be a formative focus of intellectual life in the republics then gaining independence. In this matter Andrés Bello played an important role. Bello feared that just as Latin had broken up into multiple vernaculars across the Roman Empire, Spanish might lose its transatlantic and transpacific unity spanning the peninsula and the ex-colonies. He published a *Gramática de la lengua castellana destinada al uso de los americanos* (‘Grammar of the Castilian Tongue Dedicated to the Usage of Americans’, 1847/1850) and worked up a system for spelling reform (1844/1884, p. 394).

The *Nueva Gramática de la Lengua Española* (RAE, 2009) approved by the language Academies of Spain, the Philippines, the United States of America, and 19 Latin American countries in 2007 includes diatopic (place-linked) details of variations according to “national” habits of Spanish-speaking countries not only from Spain. These changes create a larger tent for the game of standardization.

Special Purposes Vocabulary

PAUL NATION AND AVERIL COXHEAD

An important distinction to guide vocabulary teaching is the division between high-frequency and low-frequency words (Nation, 2008). High-frequency words occur often in the language and thus cover a large proportion of a text. They make up a relatively small group of words. For these reasons it is useful and feasible to give them deliberate attention during class time. This kind of attention can include direct teaching of the words, vocabulary activities, giving the words attention in intensive reading, and focusing on them when developing skill at using vocabulary strategies. Low-frequency words on the other hand are a very large group of words which provide very poor text coverage. Although they need to be learned once the learner knows the high-frequency words of the language, they do not deserve much classroom time. Learners need to learn them, but teachers should focus on strategies for dealing with them rather than on the words themselves.

For several reasons, the high-frequency words of the language are seen as being a group of around two thousand word families (Nation, 2001). A word family consists of a headword and its inflected and clearly related derived forms. One way of increasing the number of high-frequency words in the language is to develop lists of special purposes vocabulary. Because this vocabulary is of particular importance to certain groups of learners, it thus provides an opportunity for further direct vocabulary teaching and a planned deliberate focus on the vocabulary.

Working out what special purposes vocabulary learners should focus on is a part of the curriculum design process called needs analysis (Nation & Macalister, 2010). Needs analysis has the purposes of (a) quickly and efficiently meeting the needs of the learners, and (b) providing clear goals for language courses. Needs analysis can have several focuses. One of its focuses involves looking carefully at the language that learners will need to use and describing that so that it can become the basis for a language course.

The Academic Word List

Academic vocabulary exists for two major reasons (Hirsh, 2004). First, because of its Latinate nature, it signals the formality and seriousness of the subject matter. Second, it consists of vocabulary that allows academics to do the kinds of things that academics typically do. That is, it provides the kind of vocabulary that is needed to review previous research, to evaluate that research, to describe the methodology of a piece of research, to describe the results of the research, and to suggest the implications and applications of the results.

The best-known list of special purposes vocabulary is the Academic Word List (Coxhead, 2000). This is a list of 570 word families which are particularly important once learners know the high-frequency words of English and want to go on to do academic study through the medium of English. The list contains words which are frequent across a wide range of academic subjects. The list is divided into ten sublists according to the frequency and range of the words.

The following procedure was used to make the 3,600,000 token academic corpus that the list was based on. A large number of texts were collected from the four faculty areas of humanities, science, commerce, and law. Each of these faculty areas was divided into

2 SPECIAL PURPOSES VOCABULARY

seven subject areas, giving a total of 28 subject areas. Each subject area contained roughly the same total number of running words, and roughly the same balance of short and long texts.

The following criteria were used to select word families for the Academic Word List.

1. The word family could not be in 2,000 word families of *A General Service List of English Words* by Michael West (1953).
2. The word family had to occur in all four faculty divisions of the corpus, and had to occur a minimum of 10 times in each faculty division.
3. The word family had to occur in at least 15 of the 28 subject divisions of the corpus.
4. The word family had to occur with a frequency of at least 100 occurrences in the corpus.

Criterion 1 ensured that the words were not also general purpose words. Criteria 2 and 3 were range criteria, making sure that the word was a generally useful academic word. Criterion 4 was a frequency criterion, making sure that the word was common enough in academic text to make it worth learning. Applying these criteria resulted in a list of 570 academic word families which was divided into 10 sublists based on range and frequency of occurrence.

Finding Special Purposes Vocabulary

The essence of special purposes vocabulary is that it has a close connection with a particular topic area or group of topic areas. This semantic connection is reflected in the range and frequency of the vocabulary. That is, special purposes vocabulary is much more common within a particular topic area than in other topic areas. Compared to other words, a special purposes vocabulary has words of limited range and higher frequency. In the case of the Academic Word List, the words on the list are very frequent in a range of academic texts, giving a coverage of around 10% of the running words, but are infrequent in novels, providing a coverage of less than 2% of the running words.

The AWL has been used to develop further lists of specialized vocabulary. For example, Coxhead and Hirsh (2007) developed a pilot science word list of 318 word families from a corpus of first year university texts. The science list covered 3.71% of the science corpus, on average 3% higher than coverage of arts, commerce and law texts from Coxhead's (2000) academic corpus. These coverage figures indicate that the science list is technical in nature and is a useful step from general academic vocabulary to special science vocabulary. Another example of using the GSL and AWL as a framework and building a business word list comes from Konstantakis (2007). This list was created using a business English course book corpus. The resulting word list of 560 word families covered 2.79% of the specialized corpus (Konstantakis, 2007, p. 89), meaning that the combined coverage of the GSL, the AWL, and this specialized list is 93.17%. This coverage figure means that students who knew all the words on these three lists would be close to knowing almost all the words on a page in a business English course book.

Chung (2003) used these range and frequency features to develop a way of quickly finding the technical vocabulary of a subject area (Chung & Nation, 2004). Put simply, the procedure involves developing a special purposes collection of texts and a much larger general-purpose collection of texts called the comparison corpus. The comparison corpus should not contain any of the special purposes texts. For example, in Chung's study, the special purposes corpus was an anatomy text. The 2-million-word token comparison corpus included newspaper texts, novels, academic texts (but none from medicine or

anatomy), and magazines. The frequency of words in the two corpora are compared, and words which only occur in the special purposes corpus or which occur much more frequently in the special purposes corpus (Chung used a cut off ratio of 50 to 1) have a more than 90% chance of being technical vocabulary.

Another way to find special purposes vocabulary is to build a word list that starts at the beginning of students' studies and works steadily toward the vocabulary of their particular subject area. One example of such an approach is Ward (1999), who developed a corpus of 1 million running words (or tokens) using five engineering texts and extracted the most frequently occurring 3,000 words in those texts as a word list of engineering, which he then divided into three sublists: Eng1, Eng2, and Eng3. The coverage of these lists over engineering texts ranged from very high in the case of Eng1 at about 91%, down to 3–4% for Eng2, and around 1% for Eng3. Ward concludes that students specializing in engineering with reading as a primary aim would be well served to study Eng1 and Eng2, particularly in situations of limited exposure to English.

Technical Vocabulary

Chung found that 31.2% of the running words in the anatomy text were technical words. That is, almost one word in every three words in the text was a technical word. These technical words were made up of what otherwise would have been classified as high-frequency words (*neck, shoulder, heart*), academic words or low-frequency words. A large proportion of the different words in the anatomy wordlist were words that were largely peculiar to the field of anatomy—*xiphoid, carotid, subcostal*. The list contained 4,270 different word types. Chung considered that the word type was the best unit for counting rather than word families because not all members of a word family necessarily shared the technical use.

Chung also looked at an applied linguistics text using the same kind of procedure. She found that around 20% of the running words were technical words, but unlike the words found in the anatomy text, a very large proportion of the different word types, around 88%, were words that commonly occurred outside of that subject area—*language, word, negotiation*. The technical word list based on the applied linguistics text contained around 835 word types.

A Newspaper Word List

Chung (2009), using a procedure and criteria very similar to that used in the making of the Academic Word List, made a list of newspaper vocabulary based on the news sections of newspapers, and using the four divisions of local news, international news, business news, and sports news. To ensure that the words in the list would have wide range within a variety of English-medium newspapers, the newspaper corpus was made up of texts from three different English-medium newspapers from different parts of the world. The making of the corpus was a very difficult task because it involved a large number of very short texts and also involved careful checking that texts from news agencies like Reuters and API were not duplicated in different parts of the corpus. The resulting list contained 588 word families and covered around 6% of the running words in a different corpus. Proper names were excluded from the list.

Every text has its own special purposes (topic-related) vocabulary. The search for special purposes vocabulary that occurs in a range of related texts is an attempt to apply the very useful teaching principle that work on today's text should have the goal of making tomorrow's text easier.

4 SPECIAL PURPOSES VOCABULARY

Speech Acts Research

MARÍA ELENA PLACENCIA AND CARMEN GARCÍA

Introduction: Defining Speech Acts Research

Speech acts research is, in general terms, concerned with examining *what* people *do* with language in interaction, such as exchange greetings, make requests, compliment, congratulate, or express sympathy to others. They may do these things in a variety of different ways as a function of a range of contextual factors which speech acts research gives itself the aim of disentangling. For instance, in making a request, the way we ask a close friend to run an errand for us is likely to be different from the formulation we would employ with our boss when asking for a salary raise.

Speech acts research thus deals essentially with language as social action, although this notion is not restricted to speech acts research. In fact, it has different origins and is common to different approaches to the study of language in social interaction, including interactional sociolinguistics and conversation analysis (CA). The perspective on language as social action underlying speech acts research derives from speech act theory (SAT), advanced by Austin (1962), and later developed by Searle (1969, 1975, 1976).

Within SAT, speech acts constitute the basic unit of communication. They comprise three acts: the *locutionary* act, which corresponds to the literal meaning of an utterance; the *illocutionary* act, which relates to the speaker's intended meaning; and the *perlocutionary* act, which corresponds to the effect the performance of a speech act has on an audience.

The locutionary and illocutionary distinction is central to the notion of *indirect* speech acts, which refers to the widespread phenomenon of performing one particular speech act by means of another (Searle, 1975). Two basic types of indirectness have been distinguished: *conventional* and *nonconventional*. A classic example of the former is *Can you pass the salt?* Literally, this is a question about one's ability to pass the salt; however, through convention, this utterance functions as a request and it is interpreted as such in a dining scenario in English. On the other hand, if we say *This is tasteless*, expecting that someone will pass the salt to us, this utterance would be a case of nonconventional indirectness since it is not a formulation normally associated with requests; instead its meaning would need to be derived from the context.

The notion of the perlocutionary act was not given much attention within Austin and Searle's theory; yet it is central to current perspectives on communication that regard meaning as something that is negotiated in interaction. The crux of the matter is that utterances can have multiple meanings and people do not necessarily interpret utterances as they were intended. In speech act analyses, therefore, the hearer's reaction is often a useful indication of how an utterance was interpreted in a particular context.

Also distinctive of SAT is Searle's (1976) proposal that there is a set of things that we can do with language, formulated into a taxonomy with five basic categories: *directives* (e.g., requests), *expressives* (e.g., compliments), *commissives* (e.g., promises), *representatives* (e.g., statements), and *declarations* (e.g., declaring an event open). These categories have served as points of departure for innumerable speech acts studies.

Speech acts, however, constitute only one domain of study in the examination of language use in social interaction, as there are other things we do with language that are not speech acts. For example, in conversation, we use different mechanisms to take turns, to

propose a topic of conversation, and so forth, aspects of language use that are core to CA, a sociological perspective on language in social interaction.

Scope of Speech Acts Research

Speech acts research is wide ranging, covering both theoretical inquiry and empirical study of a host of speech acts in numerous languages and social contexts, constituting one of the most prolific areas within pragmatics. In relation to empirical studies, methodological issues are normally addressed within these studies; however, they have also been the object of examination *per se*.

Bearing in mind the wealth and breadth of speech acts research, a brief sketch of the whole area is provided below.

Theoretical Inquiry

Theoretical discussions have been concerned with Searle's taxonomy of speech acts, the further refinement of key concepts within SAT, and a consideration of the universality of their application. A topic that generated considerable interest in the 1980s and 1990s, and that continues to do so, is that of (in)directness. Key questions that have been addressed include what (in)directness is, whether (conventional) indirectness is a universal phenomenon, and whether indirectness is linked to politeness. Regarding the first question, for example, Blum-Kulka, House, and Kasper (1989), building on Searle (1969, 1975), proposed a detailed categorization for requests (and apologies) that distinguishes levels of directness and a range of mechanisms employed to upgrade or downgrade the force of an utterance. Downgraders include the use of politeness formulas such as *please* as well as explanations, as in *Could you please help me with this suitcase? I have a bad back*. In fact, Blum-Kulka et al.'s categorization has been the most influential to date in speech act analysis (see below), having been employed in countless studies of directives and other speech acts. A glance at empirical studies on directives, however, shows that consensus about what (in)directness is, and how it can best be described, is not unanimous.

With respect to the universality of conventional indirectness, this has been tested through a myriad of studies (see also below). Likewise, Searle's contention that there is a link between indirectness and politeness has been widely explored. Wierzbicka (1985) was among the first to contest this claim with reference to directives in Polish, highlighting the culture specificity of Searle's proposal. However, the main impetus for examining the connection between indirectness and politeness came from Brown and Levinson's (1978/1987) influential theory of politeness, which presented requests as face-threatening acts requiring redress, and conventional indirectness as a key strategy for offering such redress.

A consideration of the possibilities and limitations of SAT, particularly in its application to discourse in general, has also been a concern for a number of scholars. Discussion has centered, for example, on problems of applying the theory to stretches of talk. This relates to the absence from the theory of the hearer, which rules out any negotiation of meaning, and which in turn results in the theory offering a static view of language. Likewise, the theory has been criticized for not taking into account the social context in which different speech acts are produced and interpreted (Rosaldo, 1982).

Most empirical studies available, however, have been greatly influenced by developments in the ethnography of communication that placed the examination of speech act performance within specific social contexts in particular *speech communities* (see Hymes, 1964/1972). Indeed, Ervin-Tripp's (1976) study of directives and Manes and Wolfson's (1981) studies of compliments, both in American English, represent the earliest speech act

studies in this tradition; they paved the way for the examination of speech acts from a sociocultural perspective. Likewise, speech acts research has been shaped to some extent by developments in CA. For example, the focus in numerous speech act studies has shifted from isolated utterances to extended stretches of talk; this development has gone hand in hand with the incorporation of (some aspects of) CA methodology into speech acts research, particularly the recording of interactions, which facilitates examining extended stretches of talk.

The extent to which SAT theory can shed light on social practices associated with particular professions, as well as communication problems in social life, is something that received a certain amount of attention in the early years and continues to be explored today (see Guendouzi & Müller, 2006).

Empirical Studies

Empirical speech acts research in essence involves mapping functions to given utterances, that is, identifying the action(s) being performed from the context of use, or, conversely, mapping utterances to functions (Jacobs & Jucker, 1995). In relation to the latter, the researcher may want to find out, for example, how particular groups (e.g., German and British teenagers) carry out requests in comparable situations, so a role-play scenario may be set up to elicit the relevant linguistic realizations from a set of informants. Yet a third key concern can be described as investigating why people perform, or abstain from, certain actions, why they do them in particular ways, or both; this has taken many researchers into the investigation of (im)politeness and the management of interpersonal relations in different sociocultural contexts.

The majority of empirical studies focus on present-day use, but there is a growing number of studies taking on a historical perspective. The former examine speech acts in face-to-face interactions, in written communication as well as in a range of interactions mediated by old and new technologies including telephone, e-mail, discussion forums, and so forth. The latter focus on a range of written texts including, for example, plays and other works of fiction, as well as letters and court proceedings.

Research on speech acts has been guided by the concerns and methodologies of a number of (sub)fields. Within pragmatics, five main strands of research which are inter-linked can be identified: studies in cross-cultural, interlanguage, intercultural, variational, and historical pragmatics. A plethora of speech act studies can be found under the first two headings, particularly relating to studies carried out in the 1980s and 1990s. On the other hand, there is a growing body of work in subfields of more recent vintage, such as variational and historical pragmatics.

Cross-Cultural Pragmatics

Cross-cultural pragmatics compares “the ways in which two or more languages are used in communication” (House, 1986, p. 282), taking into account the importance of situational and social factors. The best representative of this type of studies is the Cross-Cultural Speech Act Realization Project (Blum-Kulka et al., 1989), in which the realization patterns of requests and apologies were compared across seven languages. Blum-Kulka et al. developed a research instrument (the Discourse Completion Test or DCT, a type of written questionnaire), subsequently widely adopted in the field, and a categorization framework for request and apology strategies. In terms of directness levels in requests, an important finding that came from this study is that *conventional indirectness* was overall the most frequently used strategy across the situations and languages examined. This finding prompted a large number of contrastive studies among different languages.

4 SPEECH ACTS RESEARCH

The languages that have received the most attention in this area are English, Japanese, Spanish, Arabic, and Chinese. Results from these studies have shown that while similar strategies might be used in the performance of a given speech act, the frequency and combination of strategies may differ. Additionally, they have revealed different perceptions of politeness and what is appropriate to do in a given culture.

Interlanguage Pragmatics

Scholars in this area are interested in studying what second or foreign-language learners do vis-à-vis native speakers' performance. For those engaged in speech act studies and language learning, the assumption is that "intercultural miscommunication is often caused by learners . . . falling back on their L1's sociocultural norms and conventions in realizing speech acts in the target language" (Takahashi, 1996, p. 189).

Since Wolfson and Judd's (1983) groundbreaking publication on interlanguage pragmatics, empirical research based on learners from different language backgrounds has developed in this area. Studies have mainly concentrated on comparing learner-native differences in the variety and distribution of strategies used in speech act realization, the linguistic forms selected, and the preferred politeness strategies.

A related research area is the teaching and assessment of pragmatic competence, including speech act production and interpretation (see García, 1996; Ishihara & Cohen, 2010).

Intercultural Pragmatics

Intercultural pragmatics focuses on the way people perform actions in bilingual and multilingual settings. Two seminal works in this area are Valdés and Pino (1981) and Clyne (1994). The former focused on compliment responses in a bilingual community in New Mexico, comparing the behavior of bilinguals with that of Spanish- and English-speaking monolinguals. It uncovered some features unique to the bilingual group.

Clyne's study looked at the use of directives, expressives, and commissives during meetings and other work situations in Australia. Participants included immigrants from Asia or the Pacific whose first language was not English. Clyne looked at interlingual transfer at the discourse level showing the cultural embeddedness of a number of linguistic practices.

The rationale behind many cross- (rather than inter)cultural studies is to contribute to intercultural communication by uncovering possible areas of communication conflict. However, as Spencer-Oatey (2008, p. 72) has suggested, "cross-cultural (i.e., comparative) studies do not tell us how people will necessarily behave or react when they take part in intercultural interactions."

Variational Pragmatics

Variational pragmatics is concerned with the impact of macro-contextual factors, such as ethnicity and region, on the way people do things with language. Regional variation, for instance, refers to the study of intralingual variation at the level of (sub)national varieties of a particular language (Schneider & Barron, 2008). For example, Schölmlberger's (2008) study of apologies in French French and Canadian French illustrates variation at the national level, whereas Placencia's (2008) work on requests in two varieties of Ecuadorian Spanish illustrates regional variation at the subnational level. The languages that have received the most attention in this area are Spanish, German, and English. On the other hand, the speech acts categories that have been more widely examined are directives and expressives.

Studies of requests (and other directives) have focused on variation in directness levels and the use of upgrading and downgrading lexical and morphosyntactic devices,

while recent studies have started to incorporate prosodic features. A number of studies have shown that there are similarities at the level of overall strategies (e.g., directness vs. conventional indirectness), but differences in terms of sub-strategies and the use of upgraders/downgraders. With respect to expressives such as compliments, the analysis has normally involved the comparison of semantic and syntactic formulas as well as preferred types of responses.

Historical Pragmatics

Historical pragmatics is a subfield of relatively recent development that is at the intersection of pragmatics and historical linguistics. With respect to speech acts, key questions that it seeks to answer are, for example, whether speakers of a particular language used the same range of speech acts in a period of time in the past as is employed at present and whether they used them in the same way (Taavitsainen & Jucker, 2008, p. 2). Some studies also seek to uncover norms and values that guided language use in a certain period in the past.

While initial interest in the area can be traced back to the 1970s, the publication of the first issue of the *Journal of Historical Pragmatics* in 2000 is a turning point in speech acts research from a historical perspective (see Taavitsainen & Jucker, 2008, for an overview).

Methodological Aspects

Speech acts have been examined from different theoretical and hence methodological perspectives. Within cross-cultural, interlanguage, and variational pragmatics, two favored research tools are the DCT and role play. Both allow for the setting up of comparable situations of interaction and for the control of social variables. The advantages and limitations of these methods vis-à-vis field notes from observation, recordings of naturally occurring interactions, or both have been the object of examination in several studies within the past two decades (see Golato, 2003). As a result, refinements of the two tools have been proposed (see Barron, 2003) and the need for more than one methodological perspective has been emphasized (see Cohen, 1996).

Given the nature of inquiry within historical pragmatics, alternative tools have had to be adopted, involving the exploration of small-scale and large-scale corpus-based methods. Methodological issues, such as matters of recognition and recall related to large-scale computerized searches, are currently under consideration in this area (see Jucker & Taavitsainen, 2008).

While discussion of the advantages and limitations of different methods in speech acts and pragmatics research continues, there is consensus that a combination of perspectives offered by different methodologies can provide a fuller picture or a more in-depth understanding of speech act performance; at the same time, the general view is that the choice of research method(s) ultimately depends on the aims of the study and the research questions being addressed.

The Future of Speech Acts Research

This brief overview has shown the wealth and breadth of speech acts research particularly in relation to empirical studies that have been carried out to date in multiple languages and contexts and from different perspectives. Despite the limitations of a SAT approach, the studies available have greatly contributed to our understanding of the things we do with language, what appear to be some universal features in contemporary use, and features pointing to cultural distinctiveness in language use. This, in turn, has provided

baseline data for studies on interlanguage pragmatics. Historical studies have begun to add a new dimension to our understanding of how the manifestation of certain actions has changed over time, reflecting changes in norms and values.

There is clearly a need for continuing the different lines of research outlined here to identify the (similarities and differences in the) realization of different speech acts in different languages, by different cultural groups, in different periods. While there is an abundance of studies on directives and expressives, there is scope for more studies on these categories with more diverse populations and a wider range of settings, as well as for studies on other types of speech acts. In relation to contemporary use, greater population mobility, and the development of technologies that make intercultural encounters an everyday reality, more attention needs to be paid to intercultural communication in speech act studies. Finally, with respect to methodological aspects, diachronic speech act studies have brought to the fore the interest of computerized corpus-based methods for present-day speech acts studies (see Jucker & Taavitsainen, 2008). While refinements to computerized large-scale searches are still required, such methods appear to offer an interesting avenue for large-scale speech acts research in the future.

As indicated in the introduction, a SAT approach has its limitations, since there are other domains of study of language use beyond speech acts; therefore there are aspects of language use where SAT can offer useful insight and others where other approaches are more suitable.

Speech Acts

ANDREA GOLATO AND PETER GOLATO

Linguists and language philosophers have long since recognized that language is not only used to describe states of affairs and events, but also to do certain things (for instance complaining, praising, etc.). The acts a speaker performs when uttering a sentence under normal circumstances are called *speech acts*. The term “speech act” goes back to the language philosophers John L. Austin and John R. Searle. Their theories were groundbreaking in the 1960s and beyond because of their focus on language use. Since then, speech act theory has been highly influential and has been used for language analysis not only in the fields of language philosophy and linguistics, but also in applied linguistics, psycholinguistics, and computer science. Like any approach to the study of discourse, it is not without its critics. More recent theoretical work has been aimed at overcoming some of its perceived shortcomings.

The entry is structured as follows. We first discuss what speech acts are and how they were defined by Austin and Searle. We then briefly describe some of the criticisms that are leveled at speech act theory from other discourse perspectives. In a next step, we point to more recent theoretical work trying to overcome this criticism. Finally, we provide a brief overview of the fields in which speech act theory has been used.

The Beginnings: Austin’s Description of Speech Acts

Speech act theory originated with a series of William James lectures given by Austin, an Oxford philosopher of language, at Harvard University in 1955. These lectures were published as *How to Do Things With Words* in 1962. Austin’s theory originated in his observation that, in contrast to prevailing views held at the time, declarative sentences were not necessarily always either true or false with respect to the state of affairs they described. He noted the existence of declarative sentences which, upon being uttered, seemed to perform actions. Examples of such sentences include *I now pronounce you husband and wife* when uttered at the end of a marriage ceremony, *I name this ship the USS Enterprise* when uttered while breaking a bottle of champagne across a ship’s bow, and so forth. Austin noted that for such sentences, their truth value (whatever it might be) was largely irrelevant. For Austin, what was interesting about such sentences was that by uttering them under the right conditions, the speaker performed an action. Austin called such sentences *performatives* or *performative utterances*, which he distinguished from *constatives* or *constative utterances* which describe facts and states of affairs. While constatives could be either true or false, Austin held that performatives could be either *felicitous* (or *happy*) or *infelicitous* (or *unhappy*), with the difference in felicity depending on whether the performative was uttered under the appropriate *felicity conditions*. Austin proposed four types of conditions for a performative to be felicitous:

1. The uttering of the words by the appropriate person under the appropriate circumstances has to be an accepted convention.
2. The participants involved in the procedure have to execute it completely and accurately.

The Encyclopedia of Applied Linguistics, Edited by Carol A. Chapelle.

DOI: 10.1002/9781405198431.wbeal1100

2 SPEECH ACTS

3. Any thoughts, emotions, or intentions required by the convention have to be genuinely experienced by the participants.
4. The participants must view the procedure as binding.

Austin further proposed a distinction between *explicit*, and *implicit* or *primary performatives*, the chief difference between them being that explicit performatives contained performative verbs such as *pronounce*, *name*, *declare*, and so forth, and which name the action being performed, whereas implicit or primary performatives did not contain a performative verb (e.g., *you're out!*, uttered by an umpire during a baseball game).

Finally, Austin held that in uttering language, a speaker performed three types of acts: (a) a *locutionary act*, basically corresponding to the act of phonation; (b) an *illocutionary act* such as pronouncing, naming, declaring, and so forth; and (c) a *perlocutionary act*, corresponding to the effect of the illocutionary act upon the hearer (e.g., someone is married after hearing *I pronounce you husband and wife*).

Searle's Expansion of Speech Act Theory

In his 1969 book *Speech Acts: An Essay in the Philosophy of Language*, Searle, an American philosopher of language at the University of California-Berkeley and a student of Austin's proposed an elaboration of Austin's three-part, locutionary-illocutionary-perlocutionary distinction. For Searle, speakers simultaneously accomplish four acts when they utter a phrase: (a) an *utterance act*, which is the act of uttering words, sentences, and so forth; (b) a *propositional act*, which is the act of referring and predicating; (c) an *illocutionary act* such as pronouncing, naming, declaring, and so forth; and (d) a *perlocutionary act*, which is the effect of the illocutionary act upon the hearer. Searle held that illocutionary acts were central to the study of semantics, and posited that they were rule-governed according to a set of necessary and sufficient conditions. Using the speech act of promising as an example, these necessary and sufficient conditions would be (a) a *propositional-content condition* whereby the promise must refer to a future act; (b) a *preparatory condition* in which the hearer would prefer that the speaker carry out the promise, and in which the speaker would not otherwise carry out the aforementioned promise in the normal course of events; (c) a *sincerity condition* in which by uttering the promise, the speaker genuinely intends to carry out the associated action; and (d) an *essential condition* in which the speaker intends for the promise to cause an obligation to perform the action. Searle drew a further distinction between *regulative rules*, which are rules of behavior (i.e., conventions) governing activities which exist independently of those rules (e.g., rules of traffic circulation, table etiquette, etc.), and *constitutive rules*, which both regulate and constitute behavior (e.g., rules of baseball, blackjack, etc.). For Searle, the rules of speech acts were more reminiscent of constitutive rules than of regulative rules. This led to a reformulation of the aforementioned necessary and sufficient conditions into rules.

Criticism

Searle's description of speech acts has drawn criticism over the years. One of the issues raised concerns the felicity conditions for various speech acts that Searle established. It has been noted that often, these felicity conditions actually contradict empirical behavior, that is, they contradict what can be observed in actual interaction. In her criticism of Searle, Trosborg (1995) uses the case of commands as evidence. According to Searle, one of the felicity conditions for issuing a command is that one holds a certain authority over the conversational partner and simultaneously, the conversational partner must be obliged to

follow the command. However, Trosborg (1995) points to the work of Ervin-Tripp (1976) on directives in family interactions to show that in this particular setting, commands can also be given by speakers who do not hold authority over the hearer.

In addition, it has been pointed out that the felicity conditions which are claimed to be universal have a certain ethnocentric perspective in that they often only apply to (some) Western cultures but not to Eastern cultures. This is the case for instance with the notion of volition. While volition is an important felicity condition for a variety of speech acts in American culture, it is far less important in Japanese culture. Trosborg (1995) points to research by others that indicates that in Japanese culture, social status and discernment are far more important. In other words, research indicates that felicity conditions vary with culture and are not universal as claimed by Searle.

In Searle's theory, the intention of speakers is the driving force, hence meaning is contained in individuals (Streeck, 1980) and is in turn represented and expressed in sentences. Examining the transcript of any stretch of conversation, however, it becomes apparent that people do not speak in complete sentences, yet they are able to understand each other without any difficulties. In addition for Searle, the illocutionary force a speaker is conveying is derived from the sentence the speaker produced. However, the same sentence uttered in two different contexts can have two different illocutionary forces. For instance, saying "The cake is wonderful" can function as a compliment when it is uttered shortly after tasting the first forkful of cake. When it is uttered after having consumed the last bite of cake, however, it typically functions as a request which subsequently yields an offer of an additional piece from the conversational partner (Golato, 2005; see Streeck, 1980, for additional examples).

Researchers working from a variety of other research traditions have also argued that speech act theory neglects the listener's role (e.g., Streeck, 1980; Reiss, 1985; Trosborg, 1995). Searle's model is very much a speaker-centered model in which communication flows only in one direction, namely from the speaker to the hearer. The illocutionary acts of a speaker certainly do have an effect on a hearer's actions, beliefs, and thoughts. But we know that communicative events require the active participation of the hearer, in that they have to interpret the talk directed at them (Streeck, 1980). Moreover, hearers regularly shape utterances of speakers with whom they are interacting. For instance, frowning while the conversational partner is speaking may cause the conversational partner to stop an ongoing action, to rephrase it, to clarify it, and so forth. And similarly, nodding vigorously while a conversational partner is speaking may cause him/her to cut a sentence or story short.

Recent Work

More recent theoretical work on speech act theory is aimed at addressing some of these criticisms. This work has primarily focused on perlocutionary acts in order to capture the interactive nature of speech acts. Here, van Eemeren and Grootendorst's (1984) work on expanding Searle's theory needs to be mentioned. They correctly observed that when speakers perform an illocutionary act, they do not merely want the hearer to understand the utterance, but they also want to elicit an appropriate response. Making a hearer understand would be a communicative or illocutionary act, while making the hearer react would be an interactional or perlocutionary act. According to van Eemeren and Grootendorst (1984, p. 24), perlocutionary effects can be distinguished into two parts, namely *inherent perlocutionary effects* and *consecutive perlocutionary effects*. Inherent perlocutionary effects are essentially the acceptance of the speech act by the interlocutor (such as granting a request), while consecutive perlocutionary effects consist of all other effects of the speech acts (such

as actually complying with the request, etc.). Van Eemeren and Grootendorst stress that both illocutionary acts and perlocutionary effects (and here both inherent and consecutive ones) are necessary parts of a given speech act. In line with speech act theory's grounding in intentionality, van Eemeren and Grootendorst (1984, p. 27) only consider those consecutive perlocutionary effects which the speaker indeed tried to bring about. Put differently, only intended effects are considered, while accidental effects (for instance those based on misunderstandings or mishearings) are not considered. These intended effects are then part of the speaker's meaning or intention regardless of whether they actually occur in interaction (Trosborg, 1995).

Applications of Speech Act Theory

Speech act theory has been widely used as a theoretical framework for the analysis of language. This is the case in linguistics generally, and in particular in pragmatics. In applied linguistics, it has been employed in studies on first and second language acquisition (particularly in interlanguage research), and in studies contrasting speech acts across cultures. More recently, the framework has also been adopted in experimental approaches to the study of the acquisition of pragmatics. It is also used in fields external to linguistics and philosophy, such as in computer science where it is applied in speech recognition technology.

Speech Analysis Software

ANNA MARIE SCHMIDT

Speech analysis software consists of tools that can be used in the second language (L2) classroom, by researchers or by individuals, to explore and measure important characteristics of speech production. Many of these characteristics have been shown to influence appraisal of an L2 speaker by the native English-speaking listener (Derwing & Munro, 1997). Teachers and researchers can demonstrate and measure characteristics of both acoustic and articulatory aspects of speech, including prosody, morphology, phonology, and phonetics.

Speech analysis software, however, does not interpret the analysis or highlight what is important to the L2 learner in the speech signal analysis display. Knowledge of speech acoustics is basic to the accurate use of the tools. Knowledge of the literature for speech analysis in L2 production is also invaluable. Use of speech analysis will enrich the investigation, understanding, and teaching of pronunciation and is well worth an investment of time in learning about the acoustics of speech production and the functions available in speech analysis software. Familiarity with these tools will facilitate an understanding of speech training software currently being developed for L2 speakers.

At one time, speech analysis software entailed racks of specialized equipment and dedicated computer systems. Currently, a desktop or laptop with a good external microphone and a quiet space is all that is needed for many types of speech analysis. Many Web sites explain microphone choices and specifications. (Microphones for research are usually more expensive than those required for classroom demonstration use.) Classrooms may even come equipped with computer projection software capable of supporting demonstration of acoustic and articulatory characteristics of speech in real time. Available software for speech analysis ranges from free to quite costly, but only the more costly programs require complex external hardware. Naturally, the more costly equipment usually provides more detailed and, sometimes, more accurate speech analysis. However, free programs will serve the purpose for L2 pronunciation classes and for many research purposes.

Using Speech Analysis Software in Applied Linguistics: What to Measure?

In general, measurements are made of silences, frequencies of components of the speech signal, transitions between acoustic elements, and durations of acoustic elements in the speech signal. Measurements may be made before and after instruction related to one or more of these characteristics either in a classroom or in a research setting. Measurements may also be used to observe differences between acoustic characteristics of the first language (L1) and English.

The following are brief summaries of the analyses most often employed and investigated by researchers and L2 instructors.

Analyzing Fluent Speech

Fluent speech production for an L2 speaker is speech that flows with few silent pauses or filled pauses (i.e., uhms) in the utterance. Pauses with and without fillers occur as all of us speak, but a large number of them may make comprehension of an L2 speaker's utterances more difficult for the listener (Tanner & Landon, 2009). A waveform and a spectrogram are effective for counting and measuring silences and filled pauses. Isolating and removing the fillers and pauses from recorded utterances, then playing back the original and the manipulated sentence, demonstrates the increase in fluency without pauses.

Analyzing Prosody

The term "prosody" includes the rise and fall of the pitch (intonation) carried in the vowels of an utterance, the rhythm grounded in the duration of the vowels, and the variations in loudness of the vowels across an utterance. Prosodic elements are called suprasegmentals because pitch, rhythm, and loudness changes occur in patterns across the speech sound segments. Prosodic patterns may be different for the L2 speaker's L1. Inaccurate prosody can confuse, for example, new and old information in a sentence. Derwing, Munro, and Wiebe (1998) suggested that L2 speakers who were taught about global prosodic elements were able to generalize prosody to spontaneous speech use more easily than they were able to generalize teachings about the speech segments.

Global sentence intonation tracks replicate both word stresses and phrase-final pitch declination. The tendency in English to fall in pitch at the ends of phrases and utterances, as well as the use of pitch rises on the stressed vowels of stressed syllables within words, is visible in speech analysis software pitch tracks, which can be analyzed across utterances. Pitch tracks only reflect voiced speech since the program tracks the fundamental frequency (F0), which is interpreted by the human brain as the pitch of the voice, and, thus, will display breaks in the pitch track for voiceless speech sounds. Currently, L2 speaker training using usual feedback for teaching L2 prosody is a focus of research. For example, Hardison (2004) used pitch tracks to improve English speakers' French prosody. Chun (1988) reviews software and applications of speech analysis tools to teaching intonation.

Analyzing VOT

Voice onset time (VOT) is the most studied characteristic of speech production in both L1 and L2 speech research. VOT is the time from the explosion of a stop consonant beginning a word to the beginning of voicing for the following vowel. VOT categories include pre-voiced, short-lag, and long-lag VOT. Voiceless stops in English are characterized by long-lag VOT while voiceless stops are pre-voiced or short-lag. Specific VOT values differ among languages (Lisker & Abramson, 1964). Even when differences in VOT values are small they may make a large difference in perception of stop consonants. For example, Spanish uses short-lag VOT values for voiceless /p/ while English uses long-lag VOT values. English listeners hearing a native Spanish speaker say 'peach' will often perceive 'beach'.

Analyzing Vowel Duration

Crosslinguistically, vowels tend to be longer before voiced consonants than before voiceless consonants. (Thus, the vowel /i/ in 'bead' is longer than the vowel in 'beat'.) English requires an enhancement of this difference. Speakers from some L1 backgrounds produce a smaller than necessary duration difference; speakers from other L1 backgrounds produce no difference. If an L1 has few or no final voiced consonants, a speaker of that language

is unlikely to produce a vowel duration difference in English. Without a duration difference, word pairs such as ‘mate/made’ and ‘tack/tag’ sound the same to English listeners. Vowel durations are measured from waveform and spectrographic displays.

Analyzing Spectral Characteristics of Speech: Vowels

Spectral characteristics of speech are those related to the frequency components of speech sounds, both for vowels and for sections of some consonants. Vowels can be characterized by the first two or three formants. However, Hillenbrand, Clark, and Nearey (2001) demonstrated that the transitions into and out of the vowel may be more important than the steady state of the vowel in vowel recognition. Both steady-state formants and transitions are visible and measurable in spectrographic displays.

Analysis of vowel formants can be used to understand the variety of vowels produced by an L2 speaker. English uses about 12 vowels (depending upon how “vowel” is defined); other languages use more or fewer. One pronunciation task faced by the L2 speaker is producing new or slightly different vowels in English. Analysis of vowel formants illustrates vowel accuracy as well as progress in developing vowels.

Some consonants are defined as being similar to vowels in a spectrographic analysis. The liquids and glides /r l j w/ are analyzed in terms of formants, like the vowels. For example, in order to produce an accurate /r/, the second and third formants should approach each other during production. Spectrographic analysis of /r/ formants is more accurate than perceptual analysis when evaluating /r/ production.

Analyzing Spectral Characteristics of Speech: Consonants

Most consonants are shorter and exhibit more abrupt changes in the speech signal (i.e., stops and affricates) than vowels. Fricatives, for example, differ in the frequency area containing the most acoustic energy (center of gravity). An /s/, for example, has a higher-frequency center of gravity than an /f/. English has 10 voiced and voiceless fricatives; other languages may have fewer. Analysis of an L2 speaker’s frequencies in fricative productions indicates accuracy of production.

Speech Analysis Software Programs

The simplest tools will show a waveform view of a speech signal recorded on a computer. Both Apple (through GarageBand) and Microsoft (through Sound Recorder) applications record, display, and play back a speech signal from the built-in microphone on the computer or from an external microphone. The size of the speech utterance saved is limited only by the space on the computer’s hard drive. To add spectrographic views to analysis capabilities, use a program designed for speech analysis. Interpreting waveforms and spectrograms requires knowledge of the components of the speech signal and practice using the programs. Tutorials exist for most programs. A computer sound card is necessary for recording unless the program entails the addition of external speech acquisition hardware.

Speech sound analysis programs will continue to be developed and to disappear. The following software programs (free and commercial) are in widespread use currently.

PRAAT (Boersma & Weenink, 2010) (free; PC and Mac) is one of the most used freely available programs. PRAAT capabilities range from basic waveform and spectrogram analysis to specialized complex analyses of interest to researchers. Tutorials are available both within the program and on dedicated Web sites. The PRAAT menus are organized differently from most software designed to record and explore the speech signal, requiring familiarization with program functions.

Speech Filing System (Huckvale, 2008) (free; Windows only) is a set of speech acquisition and analysis tools with tutorials. The SFS program performs recording, display, and analysis of speech signals, including waveforms, spectrograms, and frequency analysis among other functions. Also available are separately downloadable modules such as WASP for waveform and spectrographic analysis and PROREC for recording words or sentences, which can be prompted with displays on the computer monitor.

The KayPentax Computerized Speech Lab (*n.d.*) (commercial; Windows only) employs dedicated speech input hardware for controlled speech acquisition and analysis uncontaminated by computer noise. The CSL basic program provides an extensive set of analyses including waveform, spectrographic, and frequency analyses. Additional software packages are available containing databases of speech sounds (Phonetic Database and Video Phonetics Database).

Multispeech (commercial; Windows only) is a modification of the CSL for use without dedicated sound acquisition hardware. Multispeech uses the integrated computer sound card, performing the same functions as CSL. The additional CSL software packages also run on Multispeech.

TF32 (Milenkovic, 2005) (free demo and commercial; Windows only) analyzes speech frequencies in several ways. The demo version does not record but will open sound files recorded with other software programs for analysis. TF32 will display a waveform and spectrogram, will determine center of gravity for fricatives, and will display pitch, among other functions.

SIL Speech Analyzer (2007) (free; Windows only) and Wavesurfer (2005) (free; Windows only) are basic software programs that offer waveform and spectrographic analysis as well as the playback, cutting, and pasting functions found in the other programs.

Articulatory Analysis of Speech

Speech analysis software to investigate speech articulation is generally commercial. The gathering of articulatory speech data requires specialized hardware, as well as analysis software. These are dedicated systems, some adapted from medical technology, that help us understand the physical production of speech sounds. Magnetic resonance imaging (MRI) uses available technology to gather data about the structures within the oral cavity, including soft tissue (the tongue) and bone (the jaw, teeth, and palate) as the speaker lies within the magnetic chamber.

Ultrasound analysis of speech shows the soft tissue, but not the surrounding palate and jaw, as the speaker talks. Again, this is available technology applied to gathering speech data in real time. The ultrasound sensor is placed beneath the chin; the ultrasound beam of high-frequency sound waves is directed up into the oral cavity to illuminate the movements of the tongue.

Electromagnetic articulography (EMA), developed especially for speech sound research, uses sensors, temporarily attached to the tongue, jaw, and lips, to display tongue movement for vowels and consonants. The speaker sits under a helmet containing the hardware.

Motion sensor systems (optical tracking) involve the temporary attachment of sensors to body parts that move. Movements are tracked and displayed for analysis. For speech production, sensors can be attached to the lips and jaw to study lip rounding and jaw position for vowels and consonants.

Some articulation analysis systems are more transportable and are useful for individual instructional use as well as for research. The electroglottograph (EGG) is an instrument that examines vocal fold vibration for voiced and voiceless sounds and may be used for analysis of the singing voice. Electrodes are placed on either side of the larynx, registering phases of contact between the vocal folds.

Electropalatography (EPG) software displays tongue-to-palate contact for consonants. The user is fitted with a retainer-like pseudo-palate containing electrodes and connected to a computer. When the speaker's tongue touches the electrodes, dots will light up on a computer monitor display of the roof of the mouth. In this way, an accurate analysis of place of articulation can be made. EPG has been used to teach L2 speakers to modify the way they make English sounds (Gibbon, Hardcastle, & Suzuki, 1991; Schmidt & Beamer, 1998). EPG findings demonstrate that even adult speakers can learn accurate tongue positions for consonants that do not exist in the L1 phonology.

Speech Perception

SUSAN GUION-ANDERSON

It may be safe to assume that most readers have had the experience of listening to a conversation in an unknown foreign language. The reader (as listener) may have experienced speech flowing through the perceptual system with no sense of how to process it. Apart from not knowing the meaning of words, the naive listener does not know where one word begins and another ends. Some individual segments (consonants and vowels) may seem similar to native segments, while others may not. To complicate matters, two separate phonemes (contrastive segments) in the unknown language may both seem similar to a single phoneme in the native language. Prosodic features such as fundamental frequency, intensity, and duration may code lexical information in the native language but phrasal information in the foreign language or vice versa. These sorts of difference between the languages may cause the listener to misinterpret acoustic information in the speech stream. How can a listener move from complete incomprehension to successful speech processing through the course of second language acquisition? What learning mechanisms are likely involved? What factors affect the learning process? Over the past several decades, researchers have delved into these questions and developed promising theoretical frameworks and proposed explanations that continue to be evaluated.

Preliminaries

It has often been observed that some aspects of second language (L2) speech perception are easily learned, while other aspects are difficult, requiring much time and effort, if they can be learned at all. Areas of relative ease and difficulty in a specific L2 are also known to vary by the first language (L1) of the learners (e.g., different difficulties for Japanese versus Spanish learners of English), indicating that speech perception is affected by language experience. Research into the acquisition of first language speech perception corroborates this inference: infants are able to discriminate segmental contrasts not part of their ambient language, leading to their characterization as universal perceivers. However, during the first year of life, exposure to the native language causes a change in perception such that by 6 months infants begin to lose their sensitivity to non-native vowel contrasts (Polka & Werker, 1994), and by 10 to 12 months they no longer discriminate some non-native consonant contrasts (Werker & Tees, 1984).

An early developmental explanation of this perceptual reorganization during the first year of life was that infants were equipped with innate, universal speech perception abilities and that these abilities were lost or maintained depending on linguistic exposure (Eimas, 1975). However, subsequent research found that the speech perception abilities of young infants were shared with other species (Kuhl & Miller, 1978) and that human adult listeners could discriminate even the most difficult non-native contrasts under favorable conditions (Strange & Dittmann, 1984). These findings indicated that development of speech perception could be accounted for by a general auditory processing mechanism, rather than a speech-specific innate mechanism. Further, the ability to access auditory information was not lost, and, under certain conditions, it was accessible to adults. A new view developed

in which changes in the perceptual systems of infants were ascribed to higher-order cognitive changes (Kuhl, 2000). On this view, speech learning was seen as the establishment of cognitive categories and learned processing strategies.

Effects of First Language Learning on Speech Processing

Exposure to different languages results in different processing of the same acoustic input. The processing system becomes attuned to the acoustic cues that reliably distinguish linguistic categories in the L1. Thus, listeners, when presented with an array of stimuli orthogonally varying in two or more acoustic dimensions, will vary in the relative weight they assign those dimensions in speech processing. For example, Iverson et al. (2003) presented English and Japanese listeners with synthetic stimuli in which the first and second formant frequencies varied in two dimensions. Consistent with the correlation of the third formant with the English /ɹ/-/l/ distinction, native English listeners weighted the third formant more heavily in perceptual tasks. Conversely, native Japanese listeners weighted the second formant more heavily. Japanese learners of English are widely known to have difficulty with the /ɹ/-/l/ contrast. These results suggest that the cause of the difficulty lies in the learned perceptual processing in which the second formant is weighted more heavily than the third due to characteristics of the Japanese phonetic system.

Learned weighting of acoustic cues has also been documented in the prosodic domain. For example, Gandour (1983) found that language background affected the relative weighting of acoustic correlates to tone: fundamental frequency (F0) trajectories. The relative importance of the dimensions of F0 height (e.g., high, mid, or low tone) and F0 direction (e.g., rising, falling, or flat tone) varied by native language of the listener. The relative importance of the dimensions varied across the listeners as a function of language background for both tone languages (Mandarin, Thai, Taiwanese, and Cantonese) as well as a non-tone language (English). Within the domain of stress, experience with a non-stress language can lead to an inability to perceive stress in an L2. Dupoux, Pallier, Sebastián-Gallés, and Mehler (1997) found that French learners of English had difficulty discriminating words that varied only in stress placement. As French does not have contrastive stress, Dupoux and colleagues have argued that French listeners do not attend to stress placement for lexical identification.

Beyond weighting some acoustic information more heavily than others, linguistic experience can affect the weightings within perceptual cues such that perceptual sensitivity along an acoustic dimension is reduced near distributional peaks in the native language. In this vein, the native language magnet (NLM) model (Iverson & Kuhl, 1995) proposes that linguistic experience warps perceptual space. In this model, prototypical variants of a phonetic category function as “magnets” in that exemplars that are equidistant along an acoustic dimension (e.g., first or second formant frequencies in the vowel space around /i/) are not equidistant in the perceptual dimension: the exemplars in the perceptual dimension are more closely clustered around good exemplars of a phonetic category (e.g., those with formant frequencies closer to prototypical /i/) and less closely clustered around marginal exemplars. This weighting allows for efficient categorization of within-category variation in the native language but may cause distinctions in a foreign language to go unattended. In this way, learned processing of phonetic information may affect speech perception of newly encountered languages.

In addition to acoustic-auditory frameworks, cross-language perception has been considered in an articulatory framework. The perceptual assimilation model (PAM) (Best, 1995) proposes that listeners will detect similarities and dissimilarities to native sounds based on perceived articulatory properties (e.g., the constriction locations, active articulators, constriction degree, and phasing of speech sounds). The perceived distance between

the unknown foreign sounds and the closest L1 sound leads to differences in discriminability between the foreign sounds. For example, two foreign sounds assimilated to the same native category (e.g., English /ɹ/ and /l/ both assimilated to the Japanese liquid /ɾ/) will be difficult to discriminate, whereas two foreign sounds assimilated to two different native categories (e.g., English /t/ and /d/ assimilated to Japanese /t/ and /d/ respectively) will be more easily discriminated. Some foreign sounds, such as clicks (velaric ingressive sounds found in some African languages), will be assimilated as nonspeech sounds by listeners from non-click languages and, thus, easily discriminated.

Second Language Speech Processing and Learning

Malleability of Speech Processing in Adults

Attunement of the processing system to the phonetic structure of the L1 has consequences for L2 acquisition. As native speech perception proceeds in a highly automatic fashion, in which listeners extract the relevant acoustic information in practiced, or over-learned, routines, listeners are able to concentrate their processing resources on the content of the message and need allocate little attention to the form of the message. In other words, listeners are focusing on *what* is said and not *how* it is said. This automaticity is adaptive and facilitates robust perceptual processing and efficient oral communication: interlocutors can focus on communicating information and do not need to divide their attention between meaning and form. In light of these observations, Strange and colleagues (Strange & Shafer, 2008) are developing a model of speech perception in which language-specific patterns of speech perception, termed selective perceptual routines (SPRs), are proposed as the cognitive mechanism by which native speech sounds are processed and categorized. The SPRs which have been adapted to the native language may, however, be inappropriate for the L2 and continued processing of non-native sounds as native sounds may block acquisition. Thus, the second language learner has the task of detecting differences between native and non-native sounds and then developing the appropriate SPRs for the L2. As non-native listeners retain the sensory ability to detect differences in even the most difficult non-native contrasts under optimal conditions (see review in Strange & Shafer, 2008), they have the ability to detect the form of non-native speech. This ability may lead to the development of the cue weighting functions appropriate to the L2.

Empirical findings suggest that learners can indeed change aspects of their perceptual processes. Studies of both naturalistic learning and laboratory training with adults indicate that linguistic exposure can change the relative weightings of acoustic information in speech processing. Francis and Nusbaum (2002) found that native English speakers could be trained to use novel acoustic dimensions when processing Korean stop consonants. Likewise Gottfried and Beddor (1988) found that more advanced English learners of French exhibited more native-like weighting of spectral and duration cues to French vowels than less advanced learners. In the prosodic domain, Guion and Pederson (2007) found that more advanced English learners of Mandarin Chinese weighted the tonal cue of fundamental frequency slope more heavily than less advanced learners. These results indicate that speech processing systems in adults remain at least somewhat malleable and are able to adapt to the needs of L2 speech processing.

Acquisition of Second Language Speech Categories

Beyond the malleability of the speech processing system in terms of attentional weighting of specific acoustic information, learning to perceive L2 speech is widely considered to include the learning and development of new speech categories in long-term memory. Research in this area has largely focused on acquisition of segmental speech categories

(consonants and vowels) and has been guided by the framework set out in the speech learning model (SLM) proposed by Flege (1995). In line with observed changes in adult speech perception, the SLM holds that the ability to acquire new speech categories remains intact across the lifespan. Another basic tenet of the SLM is that L1 and L2 categories reside in the same phonetic space, and therefore may interact with each other. For example, L2 speech categories that are perceptually assimilated to L1 categories may develop as merged L1-L2 categories, taking on characteristics of segments in both languages. Conversely, L2 speech categories with detectable differences from the L1 are established separately. These separate L1 and L2 categories may also interact with each other through a process of dispersion in which speech categories are repelled from each other in order to maintain distinct cognitive categories. Evidence for the merger and dispersion of L1 and L2 categories is typically provided from production studies. As an example of a merged category, Flege (1987) found that French learners of English produced both English and French /t/ with a voice onset time (VOT) intermediate between the two languages. An example of dispersion was found with Quichua learners of Spanish who produced their L1 vowels differently from near monolinguals in an apparent effort to distinguish L1 and L2 vowels (Guion, 2003).

Many factors have been identified as affecting L2 category formation. Some of the more commonly discussed factors are (a) age at time of learning or development of the L1 system; (b) similarity between the L2 category and the closest L1 category; (c) the role of attention in learning; (d) salience and typological factors; and (e) development of the L2 system. Here, a brief discussion of each of these factors, along with example empirical findings, is presented.

It is generally found that an earlier age of acquisition leads to greater success in L2 learning. The domain of speech perception is no exception. For example, Tsukada et al. (2005) examined the ability of child and adult Korean learners of English to discriminate English vowels. Even though the adult and child groups had similar lengths of residence in an English-speaking country, the child group was better able to distinguish English vowel contrasts than the adult group. Findings such as these are interpreted in two major ways. One proposal is that there is a maturational critical period around puberty, before which time speech categories can be formed and after which time learning will be non-native-like (Patkowski, 1990). Another view holds that the ability to form speech categories is available to learners of all ages, but the extent of L1 development will affect the ability to learn an L2. Flege (1995) proposed that more developed L1 categories are more efficient and robust processors of acoustic information. Therefore, more developed L1 systems are less likely to detect differences between L1 and L2 sounds and, as a result, less likely to develop L2 speech categories.

The perceptual assimilation of L2 sounds as L1 sounds also affects the development of L2 speech categories. The PAM (Best, 1995) notes that L2 sounds can be assimilated as more or less good examples of L1 categories, as speech sounds but not a good fit to any L1 category, or as non-speech sounds. The SLM (Flege, 1995) predicts that the less complete the assimilation of an L2 sound to an L1 sound, the more likely a learner is to discern differences between the sounds. Discernment of differences, in this view, leads to establishment of an L2 category separate from the L1. This proposal is sometimes characterized by the summary that “new” sounds are more easily acquired than “similar” sounds. Additionally, age of acquisition is thought to modulate the likelihood of discerning differences between L1 and L2 sounds. For example, Japanese listeners tend to map both English /ɹ/ and /l/ on to the Japanese flap /ɾ/ (Iverson et al., 2003). However, English /l/ is a better example of Japanese /ɾ/ than English /ɹ/, predicting slightly more success learning English /ɹ/ than /l/ (Guion, Flege, Akahane-Yamada, & Pruitt, 2000). However,

the asymmetry is seen to more clearly benefit the formation of an English /ɹ/ category in child rather than adult learners (Aoyama, Flege, Guion, Yamada, & Akahane-Yamada, 2004).

In order to establish new speech categories, learners must come to attend to the relevant acoustic cues that encode the L2 sounds. As reviewed earlier, attention to specific acoustic dimensions can be modified in adults through naturalistic exposure and training. This is an important step in speech category formation, as attentional orienting to specific features of the incoming signal increases the likelihood of processing those features in short-term memory, for example, rehearsing in a phonological loop. Likewise, processing in short-term memory increases the likelihood of transfer to long-term memory (Logan, Taylor, & Etherton, 1996), in other words, learning. Guion and Pederson (2007; Pederson & Guion-Anderson, 2010) have demonstrated that attentional orienting toward novel, foreign-language speech categories facilitates learning of those categories. Listeners were trained on the same stimuli from an unknown foreign language under two conditions. In one condition, the listeners were oriented to a specific aspect of the speech signal and in the other condition the listeners were oriented to another aspect of the speech signal or to some other aspect such as meaning. They found that orienting to a specific aspect of the speech signal increased learning of that aspect, even when exposure was the same across groups. These findings suggest that mere exposure to L2 speech is not sufficient for learning L2 speech categories; the learner must allocate attentional resources to the specific acoustic features that encode the L2 sounds in order for learning to occur.

It has been proposed that characteristics of certain speech sounds are more likely to be attended to and subsequently learned due to their inherent perceptual salience. Burnham (1986) suggested that perceptually robust sounds are typology common, learned early in L1 acquisition, and easy to discriminate regardless of language experience. Although it proved difficult to designate sounds as robust or fragile in subsequent work, the idea of psychophysical salience has been extended to L2 learning and it has been claimed that certain acoustic cues are more likely to be employed in L2 speech perception due to their overall greater strength and availability in the acoustic signal. In this vein, Polka and Bohn (2003) put forth the peripherality hypothesis in which they propose a language-universal perceptual bias in vowel perception. They note that a vowel change from a less peripheral vowel (such as /y/, /ɔ/, or /ɛ/) to a more peripheral vowel (such as /i/, /u/, or /æ/) is more discriminable than a direction of change from a more peripheral to a less peripheral vowel and suggest that humans are predisposed to respond differently to vowels that occupy the more peripheral location within the vowel space, such that more peripheral vowels serve as reference points or perceptual anchors.

The development of the L2 linguistic system may also influence the establishment of L2 speech categories. Recently, the PAM has been extended to go beyond phonetic similarity and perceptual assimilation of unknown foreign-language sounds to encompass considerations of L2 acquisition (Best & Tyler, 2007). Specifically, linguistic knowledge of L2 phonological structure is thought to play a role in L2 to L1 category assimilation. For example, the phonotactic patterns and orthography of an L2 sound may influence its assimilation to a L1 sound: an English learner of French may consider the French uvular fricative /ʁ/ an variant of the English coronal approximate /ɹ/ due to phonological, morphological, and orthographic similarities, even though they are phonetically quite disparate. Also, development of the L2 lexicon may play a role in the development of L2 categories. As more words are learned, the functional load of an L2 contrast, especially one that was originally mapped to a single L1 category, may drive the formation of a new category to encode the phonological distinction in the L2.

Speech Perception Training and Pedagogical Implications

As a regular facet of L1 acquisition, the perceptual system becomes tuned to the needs of the ambient language. Acoustic cues which reliably encode contrastive phonological information are attended, whereas non-reliable cues come to be under-attended. This language-tuned processing becomes automatized and leads to fast, robust processing of the L1. Native listeners are adept at processing speech under difficult conditions such as noise masking or situations in which there are many concurrent conversations (Strange & Shafer, 2008). This automatic processing is necessarily language specific and will not be well suited to the needs of an L2. For the learner to successfully process speech in an L2, they must learn to attend to the relevant acoustic cues of the language and to ignore cues that are relevant for the L1 but lead to unsuccessful processing of the L2 (Iverson et al., 2003). The L2 learner possesses an adaptive perceptual system that, with considerable exposure, may accommodate an L2 and result in efficient (though perhaps not completely native-like) processing (Gottfried & Beddor, 1988). It has been suggested that the learner must detect differences between the L1 and L2 through attentional, nonautomatic processing in order for the new processing strategies to develop (Pederson & Guion-Anderson, 2010). These detected differences can then begin to form the basis of new speech categories and speech processing mechanisms, as the reoriented selective attention acts as “hooks” to bring in the relevant acoustic information for further processing and encoding in long-term memory. These observations can be brought to bear on training of L2 speech perception.

Early training studies used synthetic speech systematically varying along acoustic dimensions relevant to phonological contrasts in the L2. The use of such unnatural, constructed stimuli was aimed at orienting learners’ attention to the relevant L2 acoustic parameters. For example, Strange and Dittmann (1984) varied the formant structure from a typical /ɹ/ to a typical /l/ to make a set of training stimuli in a continuum from “rock” to “lock.” Japanese learners of English benefited from the training and were more accurate in perception of the synthetic stimuli after training. However, the trainees did not improve in their perception of naturally produced speech. It seemed that such training had succeeded in reorienting attention to the relevant acoustic cues but that a robust and generalizable processing ability had not been developed.

A type of training employing more richly varied training materials, termed “high variability” training, was developed to facilitate the formation of categories that could encompass the processing needs of naturally encountered speech. Pisoni and colleagues reported a series of experiments using naturally produced training stimuli produced by a variety of talkers in a variety of words. For example, Lively, Pisoni, Yamada, Tohkura, and Yamada (1994) found that high variability training was effective in achieving general, rather than stimuli-specific, perception of English /ɹ/ and /l/ by native Japanese speakers. The training generalized to new speakers and to new words. Additionally, the benefits of training were retained for at least six months. Further investigation found that high variability perceptual training transferred to speech production as well. Bradlow, Pisoni, Yamada, and Tohkura (1997) found that Japanese listeners trained to identify English words with /ɹ/ and /l/ not only improved in the perception of the contrast, but also were more accurate in the production of the contrast after training. High variability training has also been used successfully with prosodic elements. Wang, Jongman, and Sereno (2003) trained English listeners on Mandarin Chinese tone perception using multiple talkers and tokens. As in the case of segmental training, there were significant post-training gains in both perception and production of tone. These studies suggest that highly variable training stimuli facilitate development of robust L2 speech categories, segmental and prosodic, that can be used in both production and perception.

The results of these training studies have pedagogical implications, suggesting that classroom teachers provide explicit instruction about what to “listen for” in order to allow students to orient their attention toward relevant aspects of the L2 speech and develop their “hooks” into the L2. Once this is accomplished, learners can break out of their automatic processing routines and take in the acoustic information relevant to the L2 for further processing. After learners have developed their ability to attend to specific acoustic features relevant to the L2, high variability input may be provided to allow learners to develop robust categories. Research suggests a variety of talkers and materials should be used. Teachers may wish to provide a variety of both native and non-native speakers’ productions at this stage. Such exposure may not only improve L2 speech perception but may also benefit L2 speech production.

Spoken Word Production in Second Language Acquisition

ALBERT COSTA, ELIN RUNNQVIST, AND KRISTOF STRIJKERS

When the multilingual aphasic patient AH is asked to describe her day in Italian, she answers in the following manner: “I cannot *comunicare con* you; I am a *disastro* today” (taken from Abutalebi, Miozzo, & Cappa, 2000). This example of pathological mixing between languages dramatically reveals the situation faced by bilinguals on a daily basis: how to restrict the speech production process to only one language. In other words, how do bilinguals manage to confine their lexicalization process to the intended language without suffering major interference from the other language? Intuitively the answer to this question might seem simple, assuming that each language is stored and accessed in a separate mental dictionary. However, psycholinguistic and neuroscientific research has taught us that the dynamics of the bilingual lexicon is highly interactive, meaning that the retrieval of words in one language entails the activation of words in the other. As a consequence, the control of the language output in the bilingual speaker—often referred to as the bilingual language control issue—is central to avoid crosslinguistic errors. In this entry, we provide an overview of the investigation dedicated to bilingual language production and control in the fields of experimental psychology and cognitive neuroscience. First, we will briefly summarize the dynamics of bilingual word production to introduce the topic of bilingual language control. Second, we will focus in more detail on the functioning, development, and possible neural substrates of this language control. Furthermore, we will also report some of the collateral effects that the need of language control may have both for domain general executive control and for lexical processing. Finally, we will discuss some findings regarding processing differences between a bilingual’s two languages during speech production.

Dynamics of Bilingual Word Production

The process of producing speech involves several stages which unfold over time in a more or less sequential manner. Basically, once we know what idea to express (conceptual preparation), we have to find the right words for our message (lexical access), give them a physical shape (phonological encoding) and articulate them. A crucial tenet of models of speech production is “spreading activation.” Accordingly, it is widely assumed that the target concept (say “cat”) spreads activation to other, semantically related concepts (for example to “dog” and “mouse”) (e.g., Levelt, Roelofs, & Meyer, 1999), which in turn spread some activation to their lexical representations. Most researchers agree that all activated words will enter into a competitive process in order to get selected for production. To ensure that eventually the intended word is chosen for communication, there has to be a mechanism capable of selecting the lexical representation with the highest level of activation among all candidates.

This sample of interactivity within the system gave rise to one of the most studied questions in bilingualism: is it possible to shut off one language while speaking in the other? Extensive research has proven that the answer is negative, meaning that for a given target

concept (“cat”), not only semantically related words within the same language become activated (“dog”), but also the corresponding translation word and related words in the nontarget language (“gato,” “perro”) (e.g., Thierry & Wu, 2007). Given the parallel activation of the bilingual’s two languages and taking into account that bilingual speakers seldom commit crosslinguistic errors (e.g., Poulisse, 1999), a powerful language control mechanism must be operative ensuring the successful orchestration of word selection during bilingual speech production. Note that the principle of spreading activation between a bilingual’s languages is also broadly accepted in language comprehension. Nonetheless, the dynamics underlying language control or the extent to which this control is exerted are not necessarily similar between comprehension and production: in the latter case speakers have to actively retrieve the words from memory, while in the former case at least part of the linguistic content is already provided by the input (e.g., Costa & Santesteban, 2004b). Therefore, language control in bilingual speech production is likely to play a more central role than in comprehension.

Bilingual Language Control in Speech Production

The dominant view of the functioning of the language control mechanism in bilingual speech production is that it inhibits the activated words belonging to the language in which we do not wish to speak (e.g., Green, 1998). This process can be thought of as similar to those of everyday tasks such as driving the car where we need to suppress irrelevant information in order to perform successfully (in the case of driving to avoid accidents). Most of the evidence for this inhibitory account comes from experimental paradigms such as language switching (e.g., Meuter & Allport, 1999), picture–word interference (e.g., Mägiste, 1984) and semantic priming (e.g., Lee & Williams, 2001). Studies combining these paradigms with neurophysiological techniques such as ERPs and fMRI have observed patterns of activation that are compatible with this inhibitory account (e.g., Abutalebi et al., 2007; Christoffels, Firk, & Schiller, 2007). Nonetheless, some recent research points out that the answer to how bilinguals control their languages might be more complex and seems to depend on factors such as proficiency. In this manner, it has been observed that more proficient bilinguals show different behavioral (e.g., Costa, Miozzo, & Caramazza, 1999; Costa & Santesteban, 2004a) and neurophysiological patterns (e.g., Indefrey, 2006) in comparison to less proficient bilinguals. For example, while low proficient bilinguals are slower in returning to their L1 after speaking in an L2 than in the reverse case, high proficient bilinguals show no such asymmetry (e.g., Costa & Santesteban, 2004a). Similarly, low proficient bilinguals seem to engage more brain areas related to cognitive control when speaking an L2 as compared to high proficient bilinguals (e.g., Abutalebi & Green, 2007). This has led some researchers to propose a shift in the language control mechanism as a function of proficiency: while low proficient bilinguals rely more strongly on inhibition, the mechanism in high proficient bilinguals might be more automatic focusing directly on the relevant language for communication (e.g., Costa & Santesteban, 2004a).

Although many details regarding the exact nature and functioning of bilingual language control and how it might differ between low and high proficient bilinguals remain unanswered, a fruitful idea which emerged in recent years is that it entails domain general control mechanisms which are not exclusively bound to language. Both in patient studies (e.g., Abutalebi et al., 2000) and hemodynamic studies (e.g., Crinion et al., 2006; Abutalebi et al., 2007) it has been observed that brain areas in subcortical structures, particularly the left caudate, and brain areas in the frontal lobe, particularly the anterior cingulate cortex (ACC) and Broca’s area, are involved in tasks requiring language control. Interestingly, the same network of brain regions is involved in nonlinguistic tasks that require increased

cognitive control and attentional demands (e.g., Botvinick, Nystrom, Fissell, Carter, & Cohen, 1999). This overlap in findings encouraged researchers to assume that the same network ensuring successful control over competing behavior is also engaged for the successful control of our language output (e.g., Abutalebi & Green, 2007). The possibility of a common network subserving linguistic and executive control has led to a new line of research examining the consequences of exerting such a cognitive control on a daily basis, both for language processing itself and for other cognitive abilities.

The Bilingual Advantage in Executive Control

Indeed, the constant need to maintain two languages separate during speech production seems to have a positive impact on executive control. For instance, it has been shown that bilinguals outperform monolinguals in a variety of nonlinguistic stroop-like tasks, ranging from conflict resolution to task switching. Interestingly, this kind of bilingual advantage has been found for babies (e.g., Kovács & Mehler, 2009), children (Bialystok & Martin, 2004), older adults (e.g., Bialystok, Craik, Klein, & Viswanathan, 2004), and even for younger adults who are at the peak of their attentional abilities (e.g., Costa, Hernández, & Sebastián-Gallés, 2008; Costa, Hernández, Costa-Faidella, & Sebastián-Gallés, 2009). Perhaps because there is no general agreement about how executive control works, the origin of this bilingual advantage is not fully understood yet. Nevertheless, the most appealing manner to interpret such effects is by assuming that they originate from the need to inhibit words in the nontarget language and that this inhibitory mechanism is shared between language and domain general executive control. However, stronger and more direct evidence for this hypothesis is required, especially since some of the studies have suggested alternative explanations to that of shared inhibitory control to account for the bilingual advantage in executive functioning (e.g., Costa et al., 2009).

The Bilingual Disadvantage in Lexical Processing

While the cognitive load imposed by constantly processing two languages is beneficial for executive control, on the other side of the spectrum it has been proven to imply certain disadvantages in the linguistic domain. Recent investigations have revealed a bilingual difficulty in accessing the lexicon, reflected in slower naming latencies, decreased verbal fluency performance, and more frequent tip-of-the-tongue states in L1 for bilingual speakers compared to monolinguals (e.g., Gollan, Montoya, Cera, & Sandoval, 2008; Bialystok, Craik, & Luk, 2008; Ivanova & Costa, 2008). This negative impact of bilingualism on the speed of lexical access even in L1 could be explained as a consequence of the bilingual speaker's need to resolve competition during lexical selection (e.g., Bialystok et al., 2008). Nonetheless, an equally plausible explanation that has been put forward for the naming-cost assumes it to be a mere frequency effect in disguise: bilinguals use the words in both their languages to a lesser extent than monolinguals which makes their links between semantics and phonology weaker resulting in a slower retrieval (e.g., Gollan et al., 2008).

Another collateral effect of becoming a bilingual speaker may be the loss of lexical robustness in the first language. For example, when people learning a second language in a context of immersion are asked to produce as many words as possible in their L1 pertaining to a given category, they perform worse at the end of their study-abroad experience compared to the moment of arrival (e.g., Baus, 2010). Similarly, immersed second language learners are outperformed by classroom learners in such verbal fluency tasks (e.g., Linck, Kroll, & Sunderman, 2009). These results might be relevant for explaining the phenomenon known as first language attrition which refers to the gradual deterioration of the mother

tongue (e.g., Levy, McVeigh, Marful, & Anderson, 2007; but see Runnqvist & Costa, in press). However, just as for the bilingual naming disadvantage, it is unclear if the loss of lexical robustness is due to the inhibition of L1 words during L2 speech, or to a decrease in use of the words in L1 leading to a lower individual frequency value of these words.

Processing Differences in L1 and L2

We have so far mainly focused on the manner in which bilinguals control their language output and on the possible consequences of this control. To conclude, we will dedicate some words to another area of investigation within bilingual speech production that explores processing differences and similarities between the two languages of bilinguals. The general question here is whether the neuronal circuits involved in language processing are quantitatively, qualitatively, or both quantitatively and qualitatively distinct between L1 and L2. While some neuroimaging studies do not observe reliable differences in brain activation between L1 and L2 production (e.g., Hernandez, Martinez, & Kohnert, 2000), others report a stronger involvement during L2 production of frontal brain regions such as Broca's area (e.g., De Bleser et al., 2003). According to a recent meta-analysis these differences in hemodynamic results seem to be primarily generated by variables such as proficiency, exposure, and age of acquisition (Indefrey, 2006). Thus, there does not seem to be any qualitative neuronal dissociation between L1 and L2 production, but there might be some quantitative differences during L2 speech for late L2 learners and low proficient L2 speakers. The areas more strongly recruited by the latter group of bilinguals have been linked to a stage that occurs near the end of speech planning, namely postlexical syllabification (e.g., Indefrey, 2006). This conclusion is surprising since it seems to claim that no extra resources are required for accessing the words from the lexicon itself in a weak second language compared to a strong first language. However, a recent study using a more fine-grained temporal technique (ERPs) revealed lexical processing differences between first and second language production for early and high proficient bilinguals (e.g., Strijkers, Costa, & Thierry, 2010). This finding suggests that with the proper technique earlier and more subtle differences between L1 and L2 can be detected. It will be interesting to combine ERP findings with those of hemodynamic studies in order to have a complete spatiotemporal map of speech production in both L1 and L2 and explore the developmental trajectory of this map in function of important influences such as second language proficiency.

Concluding Remarks

In sum, bilingual speech production is still a young but vibrant area of investigation with its own specific questions as reviewed above. While extensive research has established the general ground of the dynamics of bilingual speech production, the challenge for the future is to find new methods and paradigms able to specify the exact nature of the language control mechanism and its role in explaining the collateral effects of bilingualism.

Spoken Word Recognition

HELEN FRASER

Introduction

One of the most basic aspects of learning a language is learning its words, or vocabulary. Applied linguistics rightly gives a good deal of attention to understanding the processes by which word meanings are learned, in both first and second language acquisition. But of course, words are not just meanings. Each word, as well as having a characteristic meaning, also has a characteristic sound, or pronunciation, which is just as important for learners to understand as its meaning. However, the processes by which the sounds of words are recognized tend to be given less attention in applied linguistics.

This may be because recognizing spoken words seems so easy in everyday experience. The difficult issue, it seems, is recognizing written words, especially in languages like English that have irregular spelling. However, the reason spoken word recognition seems easy is because it is highly practiced and very familiar, not because it is simple—as becomes evident in second language contexts, when learners struggle to recognize even the simplest words (such as *red* or *led*).

In fact, spoken word recognition is one of the most complex skills of human cognition, and the foundation of other crucial skills, especially (since words must be recognized before they can be reproduced) of pronunciation. Applied linguistics really needs a solid understanding of the complex nature of spoken word recognition, framed in a theory that offers practical guidance on how to respond to a variety of common problems in teaching and learning.

This entry outlines some of the key findings of research on spoken word recognition and suggests how understanding this topic is relevant to applied linguistics, especially second language teaching.

The Nature of Speech

Spoken word recognition is commonly understood via an everyday theory which sees it as a straightforward process of identifying phonemes in the acoustic speech wave, and putting them together to form meaningful words. It may seem odd to call such an apparently obvious idea a theory, but it functions as a theory in the sense that it provides a conceptual framework which guides the understanding of many observations about spoken language.

The problem is, this apparently obvious theory rests on the assumption that words in speech are discrete (have clear boundaries), invariant (essentially the same each time they are spoken), and composed of a sequence of phonemes (individual speech sounds) that are themselves discrete and invariant—in much the same way as words on a printed page are made up of discrete, invariant letters grouped into discrete invariant words (but without the irregularity of spelling).

As was discovered in the 1950s, when attempts to build computer speech systems on the basis of this everyday theory resulted in spectacular failure, these assumptions about speech are incorrect. Despite the impression given by everyday experience, speech is not

a sequence of discrete invariant phonemes, but a continuous stream of sound. In reality, there are no clear boundaries systematically segmenting the speech stream into words and phonemes (Port, 2007). In addition, unlike printed letters, which have an invariant form—for example, the letter “r” has the same shape each time it appears on this page—each individual phoneme covers a whole category of highly variable forms (called allophones), not normally noticed by ordinary speakers. For example, the phoneme /r/ is pronounced with distinctly different allophones in “rain” and “train.” In fact, phonemes show so much variation (unnoticed in everyday perception), it is fair to say they are different every time they are pronounced (Ladefoged, 2005), and in ways far more complex than suggested by the very basic examples that can be given here. The effect is that, far from being like printed letters, even the clearest speech is like very messy handwriting—except that, unlike handwriting, speech lacks gaps not just between letters, but also between words.

These characteristics of speech create what are known as the “segmentation” and “invariance” problems, which together create what became the defining question of spoken word recognition research for many decades (Perkell & Klatt, 1986): How do people categorize the continuous stream of speech into phonemes to allow word recognition—despite the segmentation and invariance problems?

Theories of Spoken Word Recognition

Currently several broad classes of theory of spoken word recognition are available to address this question. One, originating from early “motor theory” (Lane, 1965), claims that invariant units do in fact exist in speech—not in the form of acoustically defined phonemes, but rather in their underlying physical gestures (movements of tongue, lips, etc.), which the human perceptual system is geared by evolution and experience to pick up directly. A major problem faced by this class of theories is difficulty in identifying such invariant gestures in the stream of speech. So while more sophisticated versions of this idea survive as “direct realist” or “ecological” theories (Fowler, 2003), motor theory as such has mostly fallen aside. It did, however, make a lasting contribution with its concept of “categorical perception”—a postulated mechanism whereby acoustically different allophones (such as those in “rain” and “train”) can be categorized as the same phoneme (/r/) at low levels of mental processing, without conscious awareness (Repp, 1984).

A second class of theories of spoken word recognition, currently the most widely accepted, tend to be called “cognitive” in applied linguistics (e.g., Zuengler & Miller, 2006). A better term, however, is “computational,” since, following the lead of Chomsky and others, these theories model the human mind as a kind of computer (Pinker, 2003). Rather than attributing the apparent invariance of phonemes to invariant gestures, as in motor theory, these theories see spoken word recognition as a process that takes a continuous, variable speech wave as input, and computes (subconsciously) invariant representations suitable for “lexical access” (the process by which a word’s meaning is “looked up” in a “mental lexicon”; Byrd & Mintz, 2010). Categorical perception is considered an important part of this mental processing, and has been investigated extensively, as part of a research program, with considerable development in its theoretical conceptualization.

One issue that emerged early in the development of computational theories is that they require the phonological form of a word (i.e., its pattern of phonemes, syllables, and features) to be determined before lexical access—much as an orthographic form (spelling) is needed before a word’s meaning can be looked up in a physical dictionary. Reasonable as this may seem from the perspective of the everyday theory of word recognition, many experiments over the past half-century or more have shown that recognition of the meaning of entire words often precedes, overrides, or is independent of recognition of individual phonemes (Byrd & Mintz, 2010). For example, words can be recognized even if significant

portions of their phonological form are missing or altered; words containing exactly the same units of sound can be interpreted very differently depending on the context in which they are heard (not just the preceding context; the following context can retrospectively influence recognition of earlier words); parts of words, or even whole sequences of words, which sound quite clear in meaningful context, are frequently unrecognizable if heard in isolation. Such phenomena are called “real word effects,” and are similar to the more widely known “word superiority effect” of visual word recognition, which acknowledges that, in reading, it is easier for people to recognize whole words than individual letters.

Observations of real word effects, along with other considerations, have caused computational theories of word recognition to be elaborated to include processes that allow meaning and context to influence word recognition via interaction of “top-down” information (from meaning and context) with “bottom-up” information (from the acoustic speech signal). However, while there is general agreement about the need to incorporate top-down processing into word recognition models, there is considerable debate about exactly how this is achieved. The result is that there is now a range of quite complicated theories of spoken word recognition, postulating different phonological units (some reject the role of the phoneme in favor of larger units like syllables, or smaller units like phonological features) and different types of computation.

Spoken Word Recognition in Applied Linguistics

Computational theories have provided a great deal of knowledge about speech in general and word recognition in particular, and are useful for predicting and explaining observations about the spoken word recognition behavior of proficient speakers. Unfortunately, they tend to be rather less useful when applied to teaching and learning situations. Originating during the post-behaviorist split between theoretical and applied linguistics, these theories were developed through computational modeling rather than through direct engagement with teaching and learning practice. The mental processes they postulate tend to be abstract, disembodied, divorced from social and cultural context, and, most importantly, beyond the reach of conscious control, which limits their relevance to classroom teachers seeking to influence the linguistic behavior of learners. Together, these factors contribute to the situation alluded to in the introduction: word recognition is given less attention than it deserves by applied linguistics.

Another contributing factor is that, during the period computational theories were developing, language teaching practice was developing communicative methods, favoring implicit learning over explicit teaching. While this resulted in generally improved methods of teaching, it offered little guidance for teachers in how to help learners with spoken word recognition and production when explicit instruction is needed, as it often is (Derwing & Munro, 2009).

The problem is that without a good understanding of the complexities of spoken word recognition, teachers may tend, in offering explicit instruction, to fall back on the everyday theory of spoken word recognition. For example, they may try to make things simpler for learners by focusing on phonemes as if they were discrete, invariant components of words. Indeed, this was the recommended approach for some time (Baker, 1981). More recently, a number of limitations of purely phoneme-based teaching have been identified (Celce-Murcia, Brinton, Goodwin, & Griner, 2010), and teachers are increasingly recommended to focus on suprasegmentals, such as syllables, stress patterns, and intonation (Gilbert, 2005). While this has been shown (Hahn, 2004) to be more successful in some situations, it is not a panacea. After all, it is one thing to advocate teaching suprasegmentals, and another to understand exactly how to do so effectively (Fraser, 2010).

Sociocognitive Theories of Pronunciation

It is here that a third class of theories is proving valuable. “Cognitive” or “sociocognitive” theories reject the assumption that human cognition involves the kind of subconscious mechanistic processing featured by computational theories. They take a special interest in categorization as a basic, general cognitive process (Taylor, 2003), and give a central role to meaning, embodiment, and sociocultural context in understanding how the human mind categorizes reality in all its forms.

Sociocognitive theories have a lot to offer applied linguistics in general, and are being actively exploited in several areas of language teaching, including vocabulary (Tyler, Takada, Kim, & Marinova, 2005). Their take-up in relation to spoken word recognition has been slower, but involves exactly the same principles: Categorization of the variable acoustic speech wave into spoken words relies, like all other kinds of categorization, on meaning and context (see the fascinating series of experiments summarized in Cutler, 2010).

While it is difficult to give central place to meaning and context in computational theories, this is no problem in sociocognitive theories, which recognize that the “simplest” form of speech perception is not decontextualized recognition of meaningless syllables (the “nonsense words” of many computational experiments), but understanding of real, meaningful words and phrases in real, meaningful social contexts. This requires rejection of the assumption shared by both computational theories and the everyday theory: that phonemes are the basic units of speech (De Knop, Boers, & De Rycker, 2010). In fact, sociocognitive theory argues that recognition of meaningless sublexical units, such as phonemes or syllables, far from preceding word recognition, actually depends upon prior recognition of larger, meaningful units, such as morphemes, words, and phrases. While this idea may seem strange at first, it offers a simple, general account for the “word effects” that cause such difficulties for computational theories, and sees variability not as a “problem” but as an aid to perception (Dahan & Magnuson, 2006).

Pedagogical Implications

Accepting the view of sociocognitive theory that words are more basic than phonemes suggests that, when learners have trouble recognizing and reproducing words, the most useful way to help may be, not via reference to decontextualized phonemes, but via assistance with picking out similar words from different speakers in different contexts. In other words, it suggests it might be easier to teach *red* and *led* than /r/ and /l/. Once words can be recognized, they can be compared and contrasted with other words to help achieve phonological awareness (the ability to recognize, produce, and manipulate sublexical units such as phonemes and syllables).

This is similar to the order in which words come to be recognized in first language acquisition (though second language learners generally have the advantage of more mature cognitive skills). The problem is that it is easy for teachers, and even theorists, to forget how much effort is needed in first language acquisition before children can achieve even the most basic task of recognizing the same word spoken in different contexts by different people. Thus adults tend to believe that each word has “a pronunciation” (as represented in a dictionary). In fact, of course, just as each word has multiple meanings, so each also has multiple pronunciations. Think, for a simple example, of the word *probably* as pronounced by men, women, and children, as a citation form and in various sentence contexts, and so on.

As discussed above, speech is more like messy handwriting lacking gaps between words than like a printed text. Reading such handwriting cannot be achieved by looking for

individual letters to put together into words, but requires first picking out words and then reconstructing the letters. The same is true of speech—meaning necessarily comes first. Indeed, it is interesting to note that even in reading a printed page, where the segmentation and invariance problems do not apply, meaning and context frequently override “bottom-up” information from the printed letters (making it difficult, for example, to spot typographical errors in proofreading).

According to sociocognitive theories, then, the first stage of acquisition is learning to recognize meaningful words in meaningful contexts. This involves the difficult task of learning to categorize a range of very different word pronunciations as “the same word.” Only when this has been achieved can this category of pronunciations be compared and contrasted with those of other words to start the process of recognizing sublexical categories of phonemes, syllables, and so on. In other words, the first “categorical perception” that has to be mastered, according to sociocognitive theory, is not categorization of a range of different allophones as instances of a single phoneme, but categorization of a range of different pronunciations as instances of one particular word.

A further implication of sociocognitive theories of spoken word recognition is the use they make of observations about the stages through which phonological awareness is achieved. It is clear that in first language acquisition, children learn to categorize larger sublexical units, such as units of meaning, rhythm, and rhyme, long before they gain awareness of individual phonemes (Gillon, 2007). The same is true for many second language learners. This gives a rationale for the success of teaching word recognition through suprasegmentals, but also highlights the importance of basing the teaching of suprasegmentals on larger, meaningful units of sound. For example, it suggests, as a way to help learners struggling with suprasegmentals, defining syllables not as sequences of phonemes, but as parts of words, defined by patterns of rhythm and stress. Then, through comparing and contrasting those patterns, syllables can be shown to have constituents, which can be defined as phonemes.

Conclusion

The facts of spoken word recognition are usually presented via computational theories which are not just hard for teachers to understand but also of limited relevance to the practical tasks of applied linguistics. Presenting them instead via sociocognitive theory makes them more accessible, and easier to incorporate into established practices of communicative language teaching. An apparent difficulty is that understanding the sociocognitive theory of spoken word recognition means overcoming some highly entrenched but incorrect everyday assumptions, especially the view that recognition of spoken words requires the prior recognition of phonemes or other phonological units. Once this initial hurdle is overcome, however, sociocognitive theory offers a conceptual framework that can make teaching pronunciation exceptionally effective, interesting, and enjoyable.

Spoken Word Recognition in Second Language Acquisition

ANDREA WEBER AND MIRJAM BROERSMA

In order to decode the message of a speaker, listeners have to recognize individual words in the speaker's utterance. Spoken word recognition involves two central processes: multiple word activation and competition. The incoming speech calls up a set of potential word candidates that match with the unfolding input, and the activated word candidates then compete for recognition (for models of spoken-word recognition see e.g., McClelland, 1991; Gaskell & Marslen-Wilson, 2002; Norris & McQueen, 2008). As the word *steak* is heard, for example, words with similar sounds like *stay*, *stale*, *stain*, *take*, and *ache* will be considered in parallel with *steak*. The fact that words resemble one another (e.g., *drunk* and *trunk* only differ in the voicing of the initial consonant), and short words may be embedded within longer ones (e.g., *ink* in *pink*), complicates the task for the listener.

Nevertheless, recognizing spoken words is usually effortless in one's native language (L1), but the same task can be much more demanding when listening to a second language (L2). Main issues in L2 word recognition research concern the involvement of the L1 and L2 lexica and the influence of the phonological structure of the listener's mother tongue, with the focus being on lexical representations of word form.

More Lexical Activation for L2 Listeners

The processes involved in spoken word recognition are presumably universal. The question is thus not whether multiple lexical activation and competition occurs in L2 spoken word recognition, but how much of it occurs. There is ample evidence by now that part of the effort of L2 listening is caused by an increase in the competitor set for L2 listeners.

Words From the L1 Lexicon

A major factor responsible for increasing the competitor set is that L2 listeners are not able to keep their two lexica apart. That is, when listening to their second language, they cannot prevent themselves from activating words from their native language. For example, when Dutch listeners hear the English word *leaf*, they not only activate *leaf* but also the similar-sounding Dutch word *lief*, meaning 'sweet' (Schulpen, Dijkstra, Schriefers, & Hasper, 2003). Words from their native language also activate when the overlap with the second language only concerns word onset. Dutch listeners experience activation of the Dutch word *deksel*, 'lid', when hearing the English word *desk* (Weber & Cutler, 2004), and Russian listeners activate the Russian word *marku*, 'stamp', when hearing the English word *marker* (Marian & Spivey, 2003).

For L2 listeners the set of activated words is therefore not restricted to words that are phonologically similar within the second language, but is enlarged by words that are similar across the first and second language. Although the speech signal contains enough phonetic-acoustic information for the L2 listeners to know which language is being heard (e.g., the /d/ in English *desk* and Dutch *deksel* differs in voice onset time), L2 word recognition is bedeviled by parallel activation of two lexica, even for highly proficient L2 listeners.

DOI: 10.1002/9781405198431.wbeal1104

There is a ray of hope, however. Recent findings suggest that activation of the L1 is much reduced when the L1 word is semantically incongruent with a sentence's context: for example, English listeners activate English *pool* less strongly in the French sentence *Marie va nourrir la poule*, 'Marie will feed the chicken' (Chambers & Cooke, 2009; FitzPatrick & Indefrey, 2010).

Words With Easy Sounds From the L2 Lexicon

L2 listeners also suffer from an increase in lexical activation from within the second language itself. They are less efficient in deactivating unintended words than native listeners are, even when the speech does not contain any sounds that L2 listeners find particularly difficult. This is indirectly suggested by research showing that second language listeners are more affected by neighborhood density than are native listeners. Both L1 and L2 listeners find it harder to recognize words coming from a high-density neighborhood (i.e., words for which a large number of other words exist in the mental lexicon that differ by a single sound) than words from a low-density neighborhood. The more words are activated because they sound similar to the speech input, the harder it is to recognize the intended word. For L2 listeners, however, the difference between words with high- and low-neighborhood density is much larger than for native listeners (Bradlow & Pisoni, 1999).

More direct evidence for L2 listeners being less efficient in deactivating unintended words comes from a study by Rüschemeyer, Nojack, and Limbach (2008). They found that when Russian learners of German hear the German word *Tisch*, 'table', they activate *Fisch*, 'fish', long enough for its meaning and word associations to be retrieved, whereas this is not the case for native listeners of German. Interestingly, Russian listeners activate the unintended word *Fisch* even though they can easily hear the difference between the onset of *Fisch* and *Tisch*.

Words With Difficult Sounds From the L2 Lexicon

Perceiving differences between similar-sounding words is not always easy for L2 listeners. This is because L2 sound perception is often inaccurate (for an overview, see Bohn & Munro, 2007). In particular, discrimination of second language sound contrasts that are ignored in the listeners' native language may never reach native standards. Japanese listeners, for example, have notorious difficulty in distinguishing English /r/ and /l/, which both map (badly) to a single Japanese category which is phonetically between /r/ and /l/, and Dutch listeners find it difficult to perceive the difference between the English /æ/ (the vowel in *cat*) and /ɛ/ (the vowel in *desk*). These perceptual difficulties with L2 sounds affect L2 word recognition in at least three ways.

First, the distinction between minimal pairs can get lost. Dutch learners of English do not treat minimal pairs such as *flash* and *flesh* as two different words; rather, hearing *flash* also leads to the activation of *flesh* (Cutler & Broersma, 2005). Similarly, even highly fluent Spanish-Catalan bilinguals who have acquired both languages early in life show the same effect when listening to Catalan minimal pairs differing in sounds that are not contrasting in Spanish (Pallier, Colomé, & Sebastián-Gallés, 2001). Luckily, this is not a frequent problem. The number of minimal pairs in the English lexicon, for example, is relatively small, especially when compared to the number of homophones (e.g., *rain–reign*) that listeners have to handle anyway (Cutler, 2005). An increase in lexical competition due to the misperception of minimal pairs therefore occurs only rarely.

Second, words with different onsets are treated as matching in onset when perceptually difficult sounds are involved. When listeners hear a word, all words with overlapping onsets are initially activated. Thus, upon hearing the first syllable of *panda*, English L1 listeners activate not only *panda* but also *panel*, *panic*, and *pantry*, among others. As soon

as more than the first syllable is heard, the activation of the incorrect word candidates decreases, and by the time the whole word *panda* has been heard, no activation of the incorrect candidates remains (Zwitserslood, 1989). For L2 listeners, however, this initial set of competitor words is expanded by words that differ in a perceptually difficult sound contrast in the initial portion of a word. That is, for Dutch listeners, hearing English *pan*- additionally activates words like *pencil*, *penny*, and *pension* (Weber & Cutler, 2004). Similarly, for Japanese listeners, hearing *rocket* causes temporary lexical activation of *locker* (Cutler, Weber, & Otake, 2006). Since the overlap in these cases is only temporary, the initial confusion will not lead to a lasting misinterpretation of which word is being heard. Nevertheless, the extended availability of incorrect interpretations slows down the L2 word recognition process. Analysis of the English vocabulary has shown that this type of confusion occurs frequently and causes substantial added lexical competition for L2 listeners (Cutler, 2005).

Third, parts of one or more words might be mistaken for another word that the speaker did not say at all. When English L1 listeners hear the word *DEFinite*, this also temporarily activates the embedded word *deaf*. For L2 listeners, however, this can extend to cases where the speech signal does not actually contain an embedded word. Thus, for Dutch L2 listeners who hear English *DAffodil*, the nearly embedded word *deaf* is also activated, while this is not the case for English L1 listeners (Broersma & Cutler, in press). Similarly, native listeners of Dutch, which distinguishes voiced and voiceless consonants but not in word-final position, activate *groove* when they hear the near-word *groof* in biG ROOFs (Broersma & Cutler, 2008). Similarly, Spanish-Catalan early bilinguals do not distinguish accurately between Catalan words and near-words differing in Catalan-only contrasts (Sebastián-Gallés, Echeverría, & Bosch, 2005). Besides sounds, perception of suprasegmentals can be difficult for L2 listeners as well, and has been shown to affect word recognition. Spanish, for example, has minimal pairs that only differ in the location of stress, but in French, stress is not used contrastively. French learners of Spanish have great difficulties rejecting a near-word (for example *gorró*) as a word, when it is created from an existing Spanish word (e.g., *górro*, 'hat') by changing the location of stress (Dupoux, Sebastián-Gallés, Navarrete, & Peperkamp, 2008). Listeners will eventually solve the misunderstanding because an erroneous parsing of the speech signal leads to meaningless leftovers (e.g., a person who hears *deaf* in *daffodil* will be left with *-odil* as a meaningless leftover), but this still requires a time-consuming detour. Again, analysis of the English vocabulary has shown that the problem of nearly embedded words occurs very frequently (Cutler, 2005).

Difficulties of Segmenting Speech Into Individual Words for L2 Listeners

The phonological similarity of words would be less problematic if the beginning and ending of words was as clearly marked in speech as it is in written language, where white spaces indicate word boundaries. But speech is a continuous stream of sounds, and listeners have to segment the stream into recognizable units (i.e., words) themselves. Since pauses in speech regularly occur within words and are missing between words, listeners have to use other information to locate word boundaries in an utterance. Information sources for L1 listeners include rhythmic structure, phonotactics, lexical knowledge, and fine phonetic detail. Listeners are often less efficient in exploiting these language-specific information sources in their L2, mostly because their L1 segmentation strategies interfere.

Rhythmic Structure

One strategy listeners use to facilitate segmentation of running speech is based on the specific rhythmic structure of their L1. In English and Dutch, for example, most words

begin with a stressed syllable, and native listeners of those languages use stress to find word boundaries. For example, English listeners find the embedded word *mint* much faster when it is followed by a strong syllable with full vowels (as in *mintayf*) compared to when it is followed by a weak syllable with reduced vowels (as in *mintef*) (Cutler & Norris, 1988). Comparable segmentation strategies of native listeners have been found for syllable-timed and mora-timed languages like French and Japanese, respectively (Cutler, Mehler, Norris, & Seguí, 1986; Sebastián-Gallés, Dupoux, Seguí, & Mehler, 1992).

When listening to an L2, listeners tend to use the segmentation strategy they know from their L1. French listeners use the syllable-based segmentation strategy that is appropriate for French even when they are listening to English, and English listeners are not using that strategy when listening to French (Cutler et al., 1986). Similarly, native listeners of English or French persist in using L1 segmentation strategies when listening to Japanese (e.g., Otake, Hatano, Cutler, & Mehler, 1993).

Constraints on Sound Sequences

Constraints on sound sequences within syllables (so-called ‘phonotactic’ constraints) are another information source used for speech segmentation (for L1 listening research, see McQueen, 1998). For example, in English, /sl/ as in *sleep* is a legal syllable onset but /ʃl/ (‘shl’) and /ml/ are not, and while a boundary between /s/ and /l/ is possible but not required, /ʃl/ and /ml/ clearly mark a syllable boundary and possibly also a word boundary in English. German, on the other hand, requires a syllable boundary between /s/ and /l/ and between /m/ and /l/ but not between /ʃ/ and /l/. Highly proficient German learners of English use both L1- and L2-specific knowledge to segment English speech. Their knowledge of English phonotactics helps them detect the English word *lunch* in *glarshlunch*, but their interfering German phonotactic knowledge also leads to facilitated detection of *lunch* in *moycelunch* (Weber & Cutler, 2006).

Lexical Knowledge

Recognizing one word helps listeners find other words. When listeners recognize a word they know, especially when it is a longer word that is not likely to be part of another word, they expect the onset of a new word to follow. Thus, when listeners hear *anythingcorri*, they expect *corri* to be the beginning of a new word following *anything* (e.g., ‘corridor’). Both native and non-native listeners use such lexical knowledge for segmentation (White, Melhorn, & Mattys, 2010). Beneficial effects are, however, smaller for L2 listeners than for L1 listeners (Mattys, Carroll, Li, & Chan, in press). This may be because L2 listeners usually know fewer words than L1 listeners, and because L2 listeners are less certain about which stretches of speech are words and which are not.

Phonetic Detail

Fine phonetic differences in how a sound is pronounced can also provide information about word boundaries. For example, the /t/ is pronounced with aspiration in the phrase *keeps talking*, but without aspiration in *keep stalking*. English listeners use these pronunciation differences to decide which phrase they heard. L2 learners, on the other hand, cannot use this information as efficiently. Thus, both Spanish and Japanese learners of English distinguish between the two interpretations much less accurately than English native listeners do (Altenberg, 2005; Ito & Strange, 2009).

Summary and Outlook

Recognizing spoken words in one's mother tongue is easier than recognizing words in a second language, learned later in life. Of course, with a restricted vocabulary it is very difficult and sometimes impossible to understand a second language. But even if a listener knows all the words and is highly proficient in the L2, it is still harder to recognize spoken words in the L2 than in the L1. Although L1 listeners are usually not aware of the complex processes underlying word recognition, L2 listeners are often painfully aware of the complexity of the task of speech comprehension. Difficulties with L2 word recognition become even more evident during noisy listening conditions, for example, when an L2 listener tries to follow a conversation in a crowded pub. (For research on L2 listening in noise see, e.g., Golestani, Rosen, & Scott, 2009.)

As described above, one major factor responsible for the difficulty of L2 listening is that more words are competing for recognition for L2 listeners than for L1 listeners. For L2 listeners, the set of potential word candidates is multiplied with parallel activation of words from the mother tongue and of words from the second language that native listeners would not consider during recognition. The processes of lexical activation and competition in spoken word recognition are determined by phonological overlap between the speech input and words in the lexicon. But in L2 listening, the notion of phonological overlap gets a different meaning, as L2 listeners can experience overlap where L1 listeners do not.

Another factor contributing to the difficulty of L2 word recognition is that L2 listeners are less efficient than native listeners in segmenting the continuous speech stream into individual words. For L1 listeners, the task of segmentation is facilitated by numerous indications to word boundaries such as rhythmic cues, phonotactic constraints, lexical knowledge, and phonetic detail. Although L2 listeners can exploit these cues to some extent, they often cannot do so as successfully as L1 listeners.

An explanation for the difficulties of L2 listening is that listeners have already learned to speak and understand their mother tongue, and the experience with their L1 interferes with L2 acquisition (e.g., Birdsong, 1999); other explanations are biologically or socially based (see, e.g., Bialystok, 1997; Hyltenstam & Abrahamsson, 2003). Infants tune their perception very early to characteristics of their mother tongue in order to make speech processing as efficient as possible. When a second language is learned later in life, understanding the new language is then aggravated by this specialization in the mother tongue.

Yet, having an L1 already can also be beneficial for second language acquisition. Adult L2 learners have a wealth of linguistic and non-linguistic knowledge that they can bring to the task of acquiring a second language. For example, they have a set of phonemic categories that will partially overlap with the L2, they also know about words and how they are structured, they have conceptual representations for concrete and abstract objects, and they can draw on orthographic knowledge for learning new word forms. L2 learners can and do exploit all these sources for the learning task, as shown, for example, by recent research on the use of orthographic information in learning new words in an L2 (Escudero, Hayes-Harb, & Mitterer, 2008; Kaushanskaya & Marian, 2009). Luckily, the capacity for implicit learning also turns out to be larger for adult L2 learners than previously thought. Adult learners can successfully extract segmental, phonotactic, and lexical knowledge about an unknown language after a few minutes of uninstructed listening to an unfamiliar language (Gullberg, Roberts, Dimroth, Veroude, & Indefrey, *in press*).

Further, L2 listeners benefit from their L1 knowledge when listening to L2 speech produced with an L1 accent. L2 listeners recognize words more easily when the L2 speaker has the same native language as the listeners. Thus, Russian learners of Hebrew recognize Russian-accented Hebrew words faster than Arabic-accented Hebrew words (Leikin, Ibrahim, Eviatar, & Sapir, 2009), and Dutch learners of English recognize Dutch-accented

English better than Japanese-accented English (Broersma, Aoyagi, & Weber, 2010; Weber, Broersma, & Aoyagi, in press) or German-accented English (Hanulíkova & Weber, in press). These effects have been explained as long-term adaptation to the accent that the L2 listeners hear the most (i.e., the accent typical of the speakers around them).

The flexibility of lexical processing for L2 listeners still needs to be more fully understood. Currently, research on L1 listening has provided us with ample evidence for a dynamic account of spoken word recognition. L1 listeners' ability for short-term adaptation to speaker- and language-specific aspects of speech (e.g., adaptation to a bad telephone connection, a speaker with a lisp, or a regional accent), and their ability for long-term learning, now needs to be investigated in detail for L2 listeners. The outcome of this research will inform us about individual differences in language learning, and will provide insights into the interplay of flexibility and stability in the speech recognition system.

Spolsky, Bernard

ELANA SHOHAMY

Bernard Spolsky is one of the most original thinkers in the field of applied linguistics today and has had an important impact on advancing many sociolinguistic-related domains such as language maintenance and revival, language policy, multilingualism, educational linguistics, and the history, use, and ethics of language testing.

Born in New Zealand in 1932, Spolsky was educated at Wellington College, Victoria University College of the University of New Zealand, where he earned BA and MA degrees, and Auckland Teachers' Training College. He later earned a PhD at the University of Montreal.

He taught at high schools in New Zealand, Australia, and England, and at universities in Canada, the United States, and Israel. He was an assistant professor of education at McGill University (1962–4), and assistant professor of linguistics at Indiana University (1964–8) where he was the director of the English as a Foreign Language Program. At the University of New Mexico from 1968 until 1980, he was professor of linguistics, elementary education, and anthropology as well as the Dean of the Graduate School. There he established the Navajo Reading Study to study the effect of teaching reading in the pupil's native language (Spolsky, 1974).

In the early part of his career he became active in the fields of language testing (Spolsky, 1977) and bilingual education (Spolsky, 1978a), and proposed the establishment of the field of educational linguistics (Spolsky, 1978b). He also published a pioneering work on language learning theory (Spolsky, 1989).

In 1980 he was appointed professor of English at Bar Ilan University in Israel, and was active in the teaching of English in Israel, chairing the Ministry of Education professional committee. In addition to teaching and service as department chair and dean of humanities and directing scores of students for MA and PhD degrees, he founded the Language Policy Research Center at Bar Ilan University, which carried out several studies. The first was a study of the past and current sociolinguistic ecology of Jerusalem (Spolsky & Cooper, 1991). With E. Shohamy, he conducted a large-scale study of the language education policy of Israel which documented the different languages taught and used in Israeli schools (Spolsky & Shohamy, 1999); a position paper was the basis of the new national language education policy adopted by the Israeli Ministry of Education in 1996. Other studies conducted at the center included the first investigation of the academic achievement of immigrants in Israeli schools (Levin, Shohamy, & Spolsky, 2003) and, with M. Amara, sociolinguistic studies of Palestinian Arabic describing the divided village of Barta (Spolsky & Amara, 1997) and the town of Bethlehem (Spolsky, Amara, Tushyeh, & de Bot, 2000). Another area Spolsky worked in was historical sociolinguistics (Spolsky, 1985).

In 1980 Spolsky was one of three founding editors of the journal *Applied Linguistics*, and in 2001 he established the journal *Language Policy* and was its first editor.

It is language policy that defines Spolsky's work over the past two decades. Summarizing it, his book *Language Policy* (2004) offered a new approach to the field, introducing notions of ideology, policy, and practice, and focusing on human and civil rights affecting language. A follow-up, *Language Management* (2009a), examined policy in domains other than the nation-state: the family, religion, work, the military, and supranational organizations.

Spolsky is currently editing the Cambridge *Handbook of Language Policy*, preparing a special issue of *Language Policy* on language academies, and continuing studies of religious language management (Spolsky, 2003).

Spolsky has also edited handbooks and encyclopedias on language testing (Palmer & Spolsky, 1975) and educational linguistics (Spolsky, 1999). In his work on language testing, Spolsky has focused on ethical issues of impact and consequences (Spolsky, 1984). He has written about professionalism, washback, impact, ethicality, and rights in numerous articles and in his most influential book, *Measured Words* (Spolsky, 1995), which traces the history of language testing and then concentrates on the emergence of high-stakes international English tests in the USA and the UK in the 1960s. Using archival documents, he investigated hidden agendas in the development of TOEFL (Test of English as a Foreign Language) and the IELTS (International English Language Testing System), raising questions about the ethicality of these tests and their capability of measuring language. Reading the book, one begins to understand the political and economic motivations that lead to the use of tests for gatekeeping and selection of people, going far beyond the simple goal of measuring language knowledge.

His activist work has been felt in many areas but especially in his close relationship with the Māori community, where Spolsky was instrumental in the educational policy for reviving the language, consulted by the New Zealand government and various educational groups (Spolsky, 2009b).

Over the years, Spolsky has held a number of distinguished positions. He was a Senior Associate at the National Foreign Language Center of Johns Hopkins University in Washington, DC, a Senior Research Scientist at the Center for the Advanced Study of Language at the University of Maryland, and 2010 Charles Ferguson Fellow at the Center of Applied Linguistics, Washington, DC. His professional service included terms as president of International TESOL, founding secretary of the American Association of Applied Linguistics, president of the International Language Testing Association (which gave him a lifetime achievement award), and publications executive director and journal editor-in-chief of Asia TEFL since its founding.

Spolsky's is a household name among applied linguists—his work is constantly being quoted and referred to in all fields; his critical and original thinking, and his broad interests in theory, research, and practice has been inspirational to us all and should continue to be in years to come.

Sarangi, Srikant

HELEN SISSONS

Srikant Sarangi is professor in language and communication and director of the Health Communication Research Centre at Cardiff University. He is also honorary professor, Faculty of Humanities, Aalborg University (Denmark; 2009–14) and professor in language and communication at Norwegian University of Science and Technology, Trondheim (2009–11). His research interests are in discourse analysis and applied linguistics; language and identity in public life and institutional/professional communication studies.

Research

Sarangi has long argued for a practice-based platform for applied linguistics. In his 1999 book edited with Celia Roberts *Talk, Work and Institutional Order: Discourse in Medical, Mediation and Management Settings*, Sarangi proposed an interdisciplinary approach to understanding and explaining professional talk and its role in institutional settings arguing that academic research can have a practical application within institutions.

Further, as the founding editor (with Christopher Candlin) of the *Journal of Applied Linguistics*, Sarangi used the inaugural volume to call for “the widening of the applied linguistics lens” (Candlin & Sarangi, 2004).

He is well known for working closely with the health profession, among other things researching situated language use and the fairness and reliability of oral examinations in undergraduate and postgraduate medical examinations for candidates from ethnic minorities (Sarangi & Roberts, 1999). He is also a proponent of including the teaching of communication skills in all health-care programs and has written extensively on how effective communication is crucial in the prevention, treatment, and management of disease.

He established the Health Communication Research Centre (HCRC) in 1998 as an interdisciplinary initiative within Cardiff University. The center’s stated aims are to encourage dialogue between users of health care, health care professionals and other interested groups to “provide a dynamic and constructive voice in health communication research” (www.cf.ac.uk/encap/research/hcrc).

To this end, the center coordinates communication and discourse-based research in the area of health and social care. Specifically, it strives to develop new, joint research which is not only of academic excellence but also of practical relevance.

Sarangi has recently (2009) again proposed expanding the boundaries of applied linguistic and discourse analytic themes and sites as a way of recognizing the emerging interest in communication-focused activities in professions, particularly health and social care, law, therapy and counseling, business and marketing, and education. He suggests a scholarly area devoted to “language/discourse of professions” and argues in favor of an “applied linguistics of professions.” He characterizes the transition as a shift in focus from “professional discourse as a register” to “professional discourse as an expert system” with its attendant context-specific tacit knowledge sources.

History

Sarangi's interest in the English language and its uses started early. He received a distinction in BA in English before completing a master's in English and American literature. Sarangi earned his PhD in the Department of Linguistics and English Language at Lancaster University, a major international center of teaching and research in linguistics and human communication.

On the staff were Professor Norman Fairclough, a proponent of critical discourse analysis, and Professor Geoffrey Leech, who later became part of the team that compiled the British National Corpus, a 100-million-word collection of spoken and written texts designed to be representative of British English from the 1990s.

Sarangi's teaching career started in India where he lectured in English from 1979 to 1989 before spending time in London and Singapore. He joined Cardiff University in 1993 first as a lecturer, then in 1999 as reader and in 2002 he took his present position as professor in language and communication.

Publications and Research Grants

Srikant Sarangi is the founding editor of *Communication & Medicine* (Equinox); editor of *TEXT & TALK*, an interdisciplinary journal of language, discourse and communication studies (formerly *TEXT*) as well as coeditor with Christopher Candlin of the *Journal of Applied Linguistics* (Equinox).

He is the author and editor of 10 books, 5 journal special issues, and he has published over 150 journal articles and book chapters. In addition, he has presented more than 400 papers (including plenaries, invited keynotes, workshops, and colloquia) at international conferences and other forums—ranging from mainstream applied linguistics and sociolinguistics to medical and professional ones.

His major publications include *Language, Bureaucracy and Social Control* with Professor Stefaan Slembrouck (1996) which was an important contribution to the debate about the bureaucratization of language; *Talk, Work and Institutional Order: Discourse in Medical, Mediation and Management Settings* with Celia Roberts (1999) which is mentioned above; *Discourse and Social Life* with Professor Malcolm Coulthard (2000) which includes chapters from some of the most influential researchers in the field: Norman Fairclough, Ruth Wodak, Ron Scollon, Theo Van Leeuwen and Geoffrey Leech among others; and *Sociolinguistics and Social Theory* with Professor Nikolas Coupland and Professor Christopher Candlin (Coupland, Sarangi, & Candlin, 2001). His latest book is *Genetic Testing: Accounts of Autonomy, Responsibility and Blame* with Michael Arribas-Ayllon and Angus Clarke (Arribas-Ayllon, Sarangi, & Clarke, 2010).

Sarangi is also general editor (with Christopher Candlin) of three book series: *Studies in Applied Linguistics*, *Studies in Language and Communication*, and *Communication in Organizations and Professions*. He serves as an editorial board member for other journals and book series, and as a consulting advisor. Over the last ten years, he has held visiting academic attachments in many parts of the world.

He has held several project grants from funding bodies, including the Wellcome Trust, the Leverhulme Trust, and ESRC, to study aspects of health communication such as genetic counseling, quality of life in HIV/AIDS and telemedicine. He has also carried out research with particular reference to the assessment of consulting and communication skills into communication in primary care and palliative care.

Standard Language Ideology and African American Vernacular English

AKUA DUKU ANOKYE

A universal struggle is to find and exert one's own voice and to break the patterns of silence. African Americans, for example, have struggled with the desire to name and identify themselves whether using names based on their geographical beginnings, or the distasteful names used by colonizers and slave owners. In 1966 Maulana Ron Karenga, political activist, former chair of Afro Studies at Cal State Long Beach, and major proponent of Kwanzaa, a philosophy based on social and cultural change, initiated the first Kwanzaa celebration (Karenga, 1988). Part of the ritual involved the reciting of principles, among them Kujichagulia, self-determination. This was not the beginning of the struggle for self-determination, but a modern verbalization of the need to exert one's self to speak for oneself to give voice to one's own concerns.

Descriptions of Black English date back to the earliest writings about language in America. As early as the 17th century questions about the names used to represent African slaves or indentured servants arose, and until this day similar battles are being fought, for example, by African American women in the hip-hop revolution. Who will "represent" and how will they be represented?

The ability to speak "well" is a very important component in the African American experience. Tied to performance, the use of language is the means by which many African Americans achieve recognition in the community. The widespread phenomenon, used to earn the community's respect, has its roots in African verbal art. "Nommo," belief in the magical power of the word, frames the African American experience. This power spans social, political, musical, spiritual, emotional, even psychological boundaries.

Geneva Smitherman's 1994 book *Black Talk*, a dictionary of African American terms, serves to illustrate the fact that naming is an appropriate analogy for understanding the relationship between oppression and self-identifying through language. The author uses a variety of historical examples of African American discourses from music, slang, church, and popular culture to demonstrate the analogy.

Language use by African Americans has led to one of the ugliest ongoing controversies in America. From the early description of Negro dialect by "Marcel" (W. F. Allen) as phonetic decay and debasement of language on the isolated St. Helena in the Georgia Sea Islands in 1865, to Allen's patronizing 1916 *Literary Digest* editorial that describes plantation songs as full of warm-blooded sentimentality, we see the negative depiction of African Americans through their language. Even when Zora Neale Hurston published her seminal work on Negro folklore in 1935, which represented the language, culture, and discourse style as accomplishments of pride, she was deeply criticized for exposing Negroes in a distasteful light.

In spite of documented evidence, there is still today denial either that Black English exists or that it should be classified as bona fide, even though features of Black English are used in some form by a substantial number of African Americans and are often co-opted by television, advertising, and the media. Over one hundred years after the Allen description of Negro dialect, at the height of the Oakland School Board controversy naming

Ebonics as a language, the Linguistic Society of America announced a resolution affirming that whatever the name used, the language variety was rule-governed, systematic, and distinct.

Countee Cullen's 1925 poem, "Incident," depicts the pain inflicted upon an impressionable child when called out of his name. In a 1996 essay by Keith Gilyard we become acquainted with more contemporary methods of critiquing the impact of words. Gilyard is interested in the master narrative and the need to "flip the script," an adaptive response to victimization via language—the counter-story. He sets up a dialogue between expression and repression, debilitating and therapeutic, African American literature and African American rumor, to illustrate language issues. Emma Jackson writes a 1999 article that is an analysis of the same pejorative name creating havoc in Countee Cullen's poem. Based on interviews with African Americans from various backgrounds and experiences, this article attempts to examine changing definitions and perspectives.

While W. F. Allen in 1865 misunderstood the spirituals of slavery as the only form of music produced by the Negro, Amiri Baraka's 1963 work illustrates the historical development of the blues out of the shouts and spirituals resulting from a better acquaintance with English as well as greater isolation following emancipation. Gwen Pough, in a speech delivered at the 2001 American Studies Association Conference, explains that rappers speak for the people and voice their concerns. Like their earlier counterparts, the poets and the lyricists, the blues men and women, the workers, the slaves, their mission is to use language and style to "represent" the world, the complex cultural practices, styles, and innovation. As attention turns to women's language and use, we learn that Black women rappers seek to confront and change their representations, to challenge the double standard, and to claim space for themselves.

The push for standardization of any language artifact brings with it political and cultural manifestations that have particularly affected African American language. In an environment where one is being bombarded by racialized imagery and discourse, issues of intellect and identity must continually be explored. Whether it is the work of teachers in elementary classrooms or politicians on the hill, our society must undergo a repositioning of cultural and linguistic diversity that interrogates social contexts and allows multiliteracies to enrich our culture. From a pedagogical position we know that identity is expressed verbally through language variety. How does the African American Vernacular English ideology address learning language, or economic issues, or the digital divide? The challenge is that the roles of language, occurring across a wide range of sites, must strive for social justice. For African Americans who embrace their language choice as dear, their ideology is supported from beginning to end with the recognition of the power of words. What's in a name? The inalienable choice to speak for and be oneself. It is the very nature of one's identity.

Standardization in Human Language Technology

SUE ELLEN WRIGHT

The unqualified title “standardization” in the context of applied linguistics may conjure up the notion of standardizing language itself, but more commonly, language-related standards establish guidelines, frameworks, and formats designed to create, maintain, and process language resources, such as text corpora or lexicographical and terminological databases. The elaboration of standards for using language in computerized environments starts with an aspect as basic as displaying a text in a local computer application or as Web content. At the more complex end of the spectrum, it involves using words and text strings as semantic reference points to enable powerful new search capabilities on the Web. This entry examines foundational standards for representing language; both word and concept orientations to documenting lexical information; support for authoring, translation, and localization; and standards for corpus development. “Language engineering,” which can imply changing the way humans use language, has given place to the development of human language technologies that enable language to function as the crucial component of an ever-expanding knowledge infrastructure.

Standards for Language Technologies

Traditionally, industrial standards have played a role in assuring quality and consumer protection. Early standards enabled the interoperability of products in collaborative and sometimes high-risk situations; for example, specification of dimensions for hose fittings allowed firefighters from different fire companies to work together battling large fires (ANSI; see “Online Resources” below for full forms of standards acronyms). Today national, regional, and international standards specify materials, performance, process, and procedural standards, and address the quality of existing products and services. These kinds of standards frequently define guidelines for best practices. Recent trends have also moved toward functional standards that specify requirements for implementing new technologies, especially in computer environments, instead of prescribing methods associated with existing solutions. For instance, the standard for TCP/IP (Transmission Control Protocol/Internet Protocol) literally made the Internet possible (W3C). Many language-related standards fall into this second category, although some do indeed describe best practices for existing methods and products.

Baseline Standards

Language Codes

The fundamental challenge for language-related standards is the identification and representation of all human languages. These identifiers are catalogued in the ISO 639 family of language code standards and are available to the public via the ISO Concept Database (ISO CDB). Two-letter (e.g., French = *fr*) and three-letter (e.g., French = *fra* for *français*)

The Encyclopedia of Applied Linguistics, Edited by Carol A. Chapelle.

© 2013 Blackwell Publishing Ltd. Published 2013 by Blackwell Publishing Ltd.

DOI: 10.1002/9781405198431.wbeal1110

codes evolved separately in different communities of practice (terminology management, library science, and ethnolinguistic field research) long before their universal application in computing environments. Today they facilitate the display of languages on local computers and on the Web, and they control printer functions for the production of hard-copy texts. They are also used to identify oral/aural discourse and music lyrics, or the language used in a wide variety of social contexts, such as the home language of school children. They can be combined with script, character, and country codes to create language tags used to designate so-called “locales”—the regions or in some cases social environments where specific languages varieties are used (Unicode CLDR; e.g., fr-CA = Canadian French; zh-hans-CH = Chinese, simplified characters, PRC). In addition to spelling and usage rules, these tags support the localization of applications and Web pages by providing critical information such as date formats and currency values, as well as indicating which spelling and grammar checkers to use for different language varieties. The structure of locale tags represents the convergence of standards from a variety of normative bodies: Unicode Consortium “code points” for each character and symbol for a broad collection of scripts; ISO 639, 3166, and 15924 (language, country, and script codes, respectively); IANA’s implementation of the language codes; IETF Best Current Practice (BCP) 47 combination rules for generating language tags; and the W3C specification for using IETF tags on the Web and specifically in markup languages. Current language codes cover almost 7,000 ancient and modern languages, including identifiers for Esperanto and Klingon. The set is subject to ongoing revision, reflecting new insights and political realities affecting the distribution and recognition of languages worldwide.

Markup Languages

It is not the object of this entry to discuss nonhuman languages. Nevertheless, markup languages play a significant role for standards-supported language resources. The W3C Hypertext Markup Language (HTML) is the most familiar of the markup languages. At its most basic, hidden codes (called tags) indicate to a Web browser how a piece of text should be presented (displayed) on screen or in print: `<bold><italics>The Ballad of Frankie and Johnie</italics></bold>`. HTML is derived from Standard Generalized Markup Language (SGML, ISO 8879), which featured the notion of logical markup, where structural elements in a document (e.g., a title, introduction, etc.) are marked up and a second program called a stylesheet determines the layout: `<title>The Ballad of Frankie and Johnie</title>`. The powerful thing about this approach is that the developer can change the actual display throughout a document by just changing the stylesheet and not all the instances of `<title>`. XML (eXtensible Markup Language) was developed to represent data on the Web, which HTML is not powerful enough to do. It also features logical markup, which means it can represent all kinds of information about pieces of text: grammatical information, discourse-related categories, and so forth. XML is often called a *meta-markup* or *container* language because it provides framework rules and tools that can be used to create an unlimited number of formats designed to describe whatever attributes researchers or authors find interesting. XML and the related RDF (Resource Description Framework) format are consequently being used to develop a wide variety of standardized annotation schemes for marking up language resources or even replacing currently common word-processor markup.

Concept Versus Word Orientation

ISO TC 37 has historically focused on concept-oriented management of specialized language terminology. Whereas traditional lexicography examines words and their many senses,

the concept-oriented approach isolates a single sense in a specific subject field or subfield and defines the underlying concept. This view draws on a long tradition, from Aristotle (384–322 BC) onward to modern cognitive science and semiotics. Early terminologists made doctrinaire demands for “monosemy and mononymy” (univocality) in the context of specialized terminology, but terminologists today document all the potential synonyms and foreign-language equivalents associated with individual concepts, even when preferred usage is specified. Contexts and collocational usage are also critical when establishing terminological reference.

Originally intended to support standardized terminology for ISO technical committees, TC 37 standards concerning concept orientation include ISO 704 (general principles), 1087 (terminology), and 10241 (layout for ISO terminology sections and standards). Best practices for creating digital terminologies are further defined in ISO 12616 (translation-oriented terminology work) and ISO 26162 (terminology management systems), as well as a number of guidelines for terminology projects and product assessment. The concept-oriented paradigm has proven highly popular for translation and localization, especially when large numbers of domain-specific languages are involved. It has also been widely adopted by a number of other communities of practice for standardizing terms, labels, and data element names. These include metadata standards (ISO/IEC 11179 family of standards and Dublin Core), where term-like data elements used for field names and enumerated values are specified in order to support the interoperability and interchangeability of data. In a similar fashion, ECCMA and ISO 184 define cataloging labels in their *electronic Open Technical Dictionary*, which supplements ISO 8000 standards for master data quality. The Object Modeling Group’s (OMG) Semantics of Business Vocabulary and Business Rules (SBVR) project combines insights from linguistics and computer science, using natural language and formal logic to create a machine-processable environment for enforcing compliance with business rules. Long-term collaboration between ISO Technical Committees 37 and 46 is reflected in the concept-oriented approach taken for the development of thesauri and other controlled vocabularies.

Concept orientation is also fundamental to the development of domain-specific ontologies. Fueled by Sir Tim Berners-Lee’s (1955–) vision of a smart “Semantic Web,” where search engines would return highly precise and complete results for queries stated in human language, a broad and varied effort is being invested in the development of new interactive knowledge infrastructures. Here the W3C standards RDF, OWL (Web Ontology Language), and SKOS (Simple Knowledge Organization Scheme) are being implemented to assert semantic relationships between defined concepts represented by labels, which look a great deal like concept-oriented terms. Regardless of whether Lee’s grand scheme is visionary or realizable, the resulting networks are gradually improving information retrieval and processing on the Web.

The reliability of such semantic associations relies on their validity, or more specifically, on the level of trust that users can place in their defined concepts. Homonymy, synonymy, and ambiguity plague data elements and ontological labels in the same way that they do in human language. As noted above, ISO expert committees traditionally write precise definitions for terms and concepts they use in writing ISO standards, as well as for symbols and other codes. In similar fashion, concepts for data elements (called data categories in the terminology community) are defined and further specified by a variety of expert communities. In the past, these authoritative definitions have frequently been printed on paper or placed on the Web as PDF files, where they are inaccessible to machine processing. Recent policies regarding the creation of standards as databases now provide online access to ISO definitions via the ISO Concept Database. In a parallel development, the ISOcat Data Category Registry provides a working environment where experts can specify data categories on an ongoing basis, producing an ever-expanding repository of concepts and

definitions for the full range of language resources. Current coverage includes domains such as language resource metadata, morphosyntax, lexicography, terminology, and a growing list of other topics. ISOcat straddles the private and public standardized sectors by providing a working environment allowing experts to develop their data category specifications and selections (subsets of the collection) in private working groups. At the same time, ISO 12620, which defines the ISOcat model, offers the option of standardizing those selections whenever a group reaches consensus to do so. ISO 24619 on persistent identification provides guidelines for using permanently resolvable uniform resource identifiers (URIs) to ensure reliable access to entries in authoritative resources like the CDB and ISOcat. Coupled with identifiers like those used in the Dublin Core initiative, their goal is to provide reliable, speedy reference to citations from anywhere to anywhere on the Web.

Despite the traditional attention paid to terminological activities by the TC37 and 46 communities, standardizers have not ignored or deprecated lexicography. ISO 1951 on representation of entries in (lexicographical) dictionaries continues to be updated. The twin standards ISO 16642 (Terminological Markup Framework, or TMF) and 24613 (Lexical Markup Framework, or LMF) provide meta-models for the two distinct views. TMF is specifically limited to the rigorous terminological view, while LMF supports a variety of lexically oriented applications, ranging from the representation of entries in electronic dictionaries to a set of extensions specialized for morphology, semantics, and syntax, along with models for representing multiword elements and special constraints. LMF specifically excludes the representation of TMF data structures, but provides clear guidance on how the two frameworks can be linked via crosswalks between individual concepts and single sense elements in lexical resources. These standards are based on work from both TEI and the EAGLES/ISLE Multilingual Isle Lexical Entry project, which explored options for representing lexical entries in SGML and XML/RDF frameworks. Some applications actually use the terminological approach to collect concept entries that can then be reassembled into multisense lexicographical entries. For instance, IBM has developed such an in-house solution, called Translexis. The standards community is likely to include both views in the growing language and knowledge documentation infrastructure. The popular WordNet resource, for instance, incorporates aspects of both the lexical approach and terminological treatment with its use of both synsets and shallow ontological views.

Translation, Localization, and Controlled Authoring

In contrast to many of the other standards cited here, translation and localization standards are more akin to traditional industry standards in that they often define best practices and guidelines for translation services, and to a certain extent, translation products. CEN EN 15038 and its Canadian counterpart, CAN/CGSB-131.10-2008, specify criteria for certifying translation service providers, while ASTM 2575-06 provides guidelines for clients and service providers to define parameters for translation job specifications, on which quality assessment criteria can be based. None of these documents defines a clear metric for quantifying translation quality. SAE J2450 attempts such a metric aimed at evaluating the quality of translations in the automotive industry, excluding elements of style. While not a standard per se, the American Translators Association *Framework for Standard Error Marking* specifies a graduated error quantification template and is widely regarded as a model for assessing the quality of translations or for translators when viewed from the standpoint of an absolute quality scale. LISA's *List of QA Model Error Categories* engages a more holistic view of all aspects of the translation/localization product and overall process. Despite the attention paid all these standards, the issue of "inter-rater reliability" remains

a concern because different evaluators tend to produce different scores even when using a supposedly unified rating scale. Assessment standards continue to be the subject for standards development (ISO 14080), but future work must distinguish between translator competence and translation quality, in addition to linking criteria for quality assessment with parameters defining specific translation tasks. Interpreting standards are less common, although ASTM offers its comprehensive F2089-01(2007) guidelines. ISO TC 37 is developing a standard for community and public service interpreting (ISO 13611). Actual certification of translators, translation service providers, and interpreters is widely viewed as a national or regional activity. Particularly in the area of public service interpreting, local, national, and regional laws, regulations, and ethical practices vary, which poses a challenge for the development of a high-level international standard.

LISA is probably best known for its Translation Memory eXchange (TMX) standard, which has been widely implemented by developers of translation memory applications. The TMX format provides a system-neutral XML representation of paired translation units that make up translation memories exported from tools designed to assist human translators during the translation process. The interoperability of such translation memories is compromised by differences in segmentation rules used by different tools or tools settings, so TMX is augmented by Segmentation Rules eXchange (SRX), which is designed to improve leverage among translation memories. LISA's Termbase eXchange (TBX) and TBX-Basic provide platform-independent representation of terminology database material. This standard demonstrates the close interaction with other standards: ISO 16642 as a meta-model, and ISO 12620/ISOcat for the data categories used to fill out the model. Before its demise in 2011, LISA coordinated joint standardization with ISO TC 37 for TBX (ISO 30042), TMX (covered in ISO 24616, Multilingual Information Framework, or MLIF), and SRX.

Terminology management as described above sometimes results in the specification of preferred terms to be used in certain environments, such as for standards or in the software and document development process for specific companies or other enterprises. Controlled languages are more constrained because they not only specify preferred terminology. They also standardize syntax and grammar, with the goal of improving legibility, supporting the reusability of authored text chunks, and facilitating translation, even machine translation. They are most frequently used to produce documents such as maintenance manuals. A case in point is ASD Simplified Technical English, or ASD/STE. Developed originally by Boeing, ASD/STE is currently a recognized standard in the aerospace industry and is used too for the production of other defense- and manufacturing-related documents. The OASIS group also supports controlled authoring of semantically tagged, topic-related text with its DITA (Darwin Information Typing Architecture). Developed in tandem, DITA and OASIS' XLIFF (XML Localisation Interchange File Format) standard support efficient localization of dynamically changing textual content.

Annotation Frameworks for Text Corpora

XML has also been used to create annotation schemes designed to express or describe textual and semantic features in text corpora and other language resources. A number of players have contributed to this effort, beginning with the Text Encoding Initiative (TEI) in 1994, working at that point with SGML. A sequence of US/European research projects (EAGLES/ISLE and CLARIN) have gone on to develop annotation schemes for cross-platform, cross-application representation of aspects of digitized text. These activities have fed back into the work of ISO TC 37, SC 4. Starting with a basic framework for representing feature structures, current solutions focus on morphosyntactic, semantic, syntactic, and linguistic annotation, including markup for discourse structures and time-related elements.

The ISOcat DCR cited earlier functions as a central repository for data category concepts used in the various related tagging systems and annotation schemes. This work contributes to an overall goal to create an “integrated and interoperable research infrastructure for . . . language resources” (CLARIN).

In the context of corpus linguistics, one of the intrinsic artifacts of alphabetical languages that facilitates the implementation of automatic processing strategies is the presence of white space between lexical units. Languages like Russian and German that merge smaller words to form long single words pose some problems in this regard, but the major challenge is with non-white-space languages like Japanese, Chinese, and Korean. In the face of extensive research being conducted on word segmentation and named entity recognition, ISO 24614 provides a discussion of general principles as well as guidance specifically for Chinese written texts.

Terminology Policy

Language planning topics are dealt with elsewhere in this Encyclopedia. Certainly one component of language planning and policy involves the regulation or at least the strong recommendation of specialized terminology for many individual domains and language communities. Originally published as an Infoterm report, the UNESCO *Guidelines for Terminology Policies* (2005) has been further elaborated as ISO 29383, *Terminology Policies: Development and Implementation* (2010). The document provides policy makers in governments, administration, nonprofit, and commercial organizations with guidelines and a methodology for developing and implementing a comprehensive policy or strategy concerning the planning and management of terminology.

Standard Setting on Language Tests

DORRY KENYON

Standard-setting practices are becoming common in language testing in cases where test developers and users want to *link* student performances on language tests to verbally defined levels of proficiency, such as the levels of the Council of Europe Framework of Reference for Languages (Council of Europe, 2001). Such practices draw upon the psychometric literature, in which standard setting “refers to the process of establishing one or more cut scores on tests . . . [that] function to separate a test score scale into two or more regions, creating categories of performance or classifications of examinees” (Cizek & Bunch, 2007, p. 13). Such categories are intended to provide interpretive meaning to examinees’ test performances, whether classifying an examinee’s performance as “pass” or “fail,” or “novice,” “intermediate,” “advanced,” or “superior,” particularly for decisions that are of some consequence to examinees and score users. Although psychometric and statistical tools are used in standard setting, the process itself is a socially moderated procedure (i.e., determined by judgments made by individuals in a social context). Professionals in standard setting investigate and develop technical procedures aimed to limit randomness, estimate its extent, and ensure that the final outcome is the result of a principled synthesis of relevant perspectives.

Several features of the best standard-setting methodologies help minimize arbitrary outcomes. Fundamental to these methods is the use of panels of large numbers of stakeholders whose knowledge and experience make them qualified to serve as panelists. The analysis and reporting of data from both independent judgments and consensus-building processes documents both variability among panelists and the extent to which consensus was reached. For example, internal replications, such as dividing a larger group of panelists into subpanels and analyzing and reporting variation within and across these subpanels, provide evidence of the generalizability of the outcome. Careful documentation of each study includes the background and qualifications of panelists, detailed description of the procedures and materials used, the analysis of the data and results, and an evaluation by participants of their experience. Such documentation allows others to judge the quality of the study, provides the required information to replicate the study with another set of panelists, and presents evidence to support the final results. Researchers have investigated a variety of methodologies, and methodologies developed more recently (such as book-marking and body of work) recognize the need for panelists to draw on their experience with individuals similar to the test takers to evaluate direct observations of student performances (whether on selected response or constructed response items) and to be presented with a judgmental task that reduces cognitive complexity to the greatest extent possible.

The Historical Social Context

Current knowledge and practice in standard setting were originally developed through psychometric research in the context of certification testing. While the fourth edition of *Educational Measurement* contains a dedicated chapter on “Setting performance standards” (Hambleton & Pitoniak, 2006), the primary discussion of the topic in the third edition occurred in “Certification of student competence” (Jaeger, 1989). In the second edition,

The Encyclopedia of Applied Linguistics, Edited by Carol A. Chapelle.

DOI: 10.1002/9781405198431.wbeal1113

more sophisticated approaches to standard setting were confined to an important footnote in Angoff's (1971) chapter on "Scales, norms, and equivalent scores."

The recognition that the attribution of competency is also a social construct that may have serious consequences for individuals, groups, institutions, agencies, and other bodies implies that, implicitly or explicitly, a standard-setting study is normally done on behalf of, and to provide information to, some policy council or other body that will ultimately authorize the results. Carson (2001) points out that "[c]ertification is credentialing by either a governmental authority or a private entity" (p. 427). Although this point may not be explicitly stated in the language testing literature, it is important to recognize that whenever a linking is done between performances on a language test and performance level descriptors, some authority or entity ultimately stands behind the outcome, whether an identified formal body or the test publisher who makes the results of a study public. Because attainment of performance levels may have serious consequences for test takers or others, the undertaking of any standard setting must be done with due diligence. In the best situation, all who are involved in the process explicitly recognize that the results of the study are recommendations to a final body that gives power to the outcome and that the process is not conducted in a social vacuum.

Referring to decisions made based on results of competency tests, Jaeger (1989) pointed out, "To the extent that invalid inferences are exposed, and measurement practices that reduce validity are eliminated, the value of competency testing can be increased and societal damage resulting from competency testing can be minimized" (p. 511). In the current climate of accountability for educational outcomes in the United States, the use of defensible standard-setting procedures has perhaps even greater weight and continues to generate a growing body of research (see, for example, Philips, 2001). The needs of the National Assessment of Educational Progress (NAEP), which provides US policy makers with "The Nation's Report Card" and interprets student performance as basic, proficient, or advanced, has provided resources for much scholarly research on comparing and developing standard-setting methodologies (Loomis & Bourque, 2001). The "No Child Left Behind" legislation of 2002 required states to define performance expectations for students and to test students to determine attainment of those expectations. This requirement has led to widespread application of standard-setting methodologies in the United States in a very high-stakes context.

Examples of Linking Language Tests to Proficiency Level Definitions

Standard-setting methodologies from the psychometric tradition are being used to link language tests to proficiency level definitions. First, in the European context, the publication of the Common European Framework of Reference (CEFR) (Council of Europe, 2001) and its widespread influence created a need for test developers to link performances on their assessments to the CEFR levels. To provide guidance, the Council of Europe produced a *Manual for relating language examinations to the Common European Framework of Reference for Languages (CEFR)* and *Reference supplement* (Council of Europe, 2009), available online. This manual first appeared as a preliminary pilot version in 2002–4. According to the introduction, the aim of the manual

is to help the providers of examinations to develop, apply and report transparent, practical procedures in a cumulative process of continuing improvement in order to situate their examination(s) in relation to the Common European Framework (CEFR). The Manual is not the sole guide to linking a test to the CEFR and there is no compulsion on any institutions to undertake such linking. However, institutions wishing to make claims about

the relationship of their examinations to the levels of the CEFR may find the procedures helpful to demonstrate the validity of those claims.” (p. 1)

Two examples of the use of the manual to link performances on the Test of English as a Foreign Language (TOEFL) to the CEFR levels are readily available online (Tannenbaum & Wylie, 2005, 2008).

Second, in the United States, the requirement of the 2002 “No Child Left Behind” legislation resulted in annual assessment of all English-language learners against English-language standards. The annual testing is to provide evidence that English-language learners are growing in their acquisition of the English language. While individual states determine the test that they will use, performances on all tests must be linked to state-adopted English-language development standards. An example of how linking was done for the (currently) 25 member states of the WIDA Consortium is provided in Kenyon (2006).

Issues and Directions in Standard Setting

Fundamentally, standard setting provides evidence concerning the meaning of scores. In language assessment, such meanings are often stated in terms of verbal descriptions of language proficiency levels such as the CEFR, the Proficiency Guidelines of the American Council on the Teaching of Foreign Languages, the Interagency Language Roundtable Language Skill Level Descriptions, or English-language proficiency levels described in state standards such as the WIDA ELP Standards. Providing evidence linking scores to their interpretations is an important part of developing a validity argument for test score use or an assessment use argument (Bachman, 2003). Therefore, standard setting is an essential process in a validity argument for test scores intended to index levels on a scale consisting of verbal descriptors. Three significant challenges need to be addressed if standard-setting studies are to play the role that they should in the validation of language assessments.

First, the necessary resources need to be allocated in test development projects because conducting such studies is resource intensive and no single study may be deemed definitive. Language test developers who seek to relate performances on their tests to proficiency levels will need to include the time, money, and personnel resources to conduct such studies before their tests become operational. Indeed, if providing such score interpretations is the primary purpose of the assessment (as in the case of the WIDA Consortium’s ACCESS for ELLs®), this goal will guide many decisions in the design of the test. Nevertheless, this step of the test development and validation process will definitely increase the burden on test development resources.

Second, because an evaluative decision needs to be made about the appropriateness and adequacy of the results of standard-setting studies, language test developers need to be clear as to what body or entity will ultimately stand behind the use of links between test performances and their interpretation based on standard setting. In the high-stakes case of ACCESS for ELLs®, the highest policy-making committee of the WIDA Consortium must approve and authorize the published links and the interpretation of performances on its test in terms of the Consortium’s proficiency levels. In contrast, the CEFR manual appears unclear about what policy body, besides the test developer, is ultimately responsible for standing behind links established through standard setting.

Third, language testers need to contribute to the continuing research to understand and improve the process of standard setting. With a proliferation of standard-setting methodologies being used by language testers in Europe, new approaches to investigating standard setting are also appearing. In the US psychometric literature, research studies comparing

alternative methodologies routinely solicit data from participants. Yet analyses of panelists' comments tend to be superficial and quantitatively oriented. The interdisciplinary nature of language testing holds promise that more qualitative analyses of such data will begin to appear. A first step in this direction was demonstrated by Papageorgiou (2010), whose research sheds light on the potential use (or misuse) of impact data when linking test performances to proficiency levels. The sharing with standard-setting panelists of how many students will fall into each performance level if the links are set as proposed by the outcome of the study is typically recommended as a "reality check." This practice has its origin in US accountability testing. State policy decision makers do not expect drastic shifts in the numbers of students in each category from year to year, and may be especially concerned about the number of students in the bottom category. However, when language testers use standard setting to link test performances to proficiency levels, impact data can be very confusing when the recommendations of panelists are not confirmed. For example, panelists may doubt the process they followed if students in their institution's level C1 class are being designated as B2, even though an alternative explanation could also be made that the C1 class was mislabeled.

Qualitative studies by language testers will clarify panelists' decision-making processes and provide guidance as to recommendations on the composition of panels. Discourse analysis of consensus-building discussions may also shed light on how to improve procedures to avoid, for example, dominance by an individual in swaying the opinion of a group. The social nature of the process makes it ripe for the insights applied linguistics can provide. For this research to have the greatest impact, results will need to be accessible to researchers in the more psychometric tradition as well. Similarly, language testers using standard-setting methodologies need to keep abreast of the latest research in standard setting from the psychometric tradition.

Stansfield, Charles

DANIEL J. REED

Dr. Charles W. Stansfield is president of Second Language Testing, Incorporated (SLTI), a thriving test-development company that he created in 1994, which has clients in government, education, and in the private sector. He has been a leading authority in the field of second language testing since the 1970s, being especially well known for his innovative work in language test development and for his significant contributions to the professionalization of language testing as a field. In particular, he played a leading role in the development of tests for more than 25 languages and dialects, worked hard to establish the International Language Testing Association (ILTA), and served as that organization's first president (1992–3). He has held several major positions over the years including program administrator for the *Test of English as a Foreign Language* at Educational Testing Service (ETS) in Princeton, NJ (1981–6), director of the Foreign Language Education and Testing Division and director of the ERIC Clearinghouse on Languages and Linguistics at the Center for Applied Linguistics (CAL) in Washington, DC (1986–94), and president of SLTI since 1994. In 2007, Stansfield was presented with the ILTA Lifetime Achievement Award.

Education and Early Years (1968–81)

Stansfield's interest in language testing did not fully develop until after he had completed graduate school. Throughout his undergraduate and graduate studies, he passionately pursued a number of other areas related to language learning. In the process, he earned a BA in Spanish (1968), an MA in foreign language education (1969), an MS in teaching English as a foreign/second language (1970), and a PhD in foreign/second language education (1973)—all from Florida State University. He studied abroad in Valencia in Spain, Bogotá in Colombia, and Monterrey in Mexico. Thus, Stansfield emerged from graduate school with extensive training in three distinct fields: Spanish, English as a second language (ESL), and bilingual education. Such a diverse background was considered unusual at the time, but it turned out to be surprisingly appropriate for the career path that he followed.

After leaving Florida State University, Stansfield taught Spanish at the University of Colorado from 1970 until 1981, ascending the ranks from instructor to associate (tenured) professor. In 1976–7, he spent his sabbatical taking courses in statistics and measurement. During this period, he also started and directed a Peace Corps Training Center in Managua, Nicaragua (1978), where he became a certified oral proficiency interviewer, and director of the University of Colorado Study Abroad Program in Xalapa, Mexico (1974–5) and in Valencia, Spain (1973). Like many good bilinguals, he occasionally did translations and informal interpreting.

At ETS (1981–6)

At ETS, Stansfield became widely known as a very competent test program administrator. As the associate director of language programs at ETS, and research administrator for the

Test of English as a Foreign Language (TOEFL), Stansfield's ESL training, combined with the skills and knowledge of testing he had attained after graduate school, made him an ideal supervisor for the projects that were being conducted at ETS at the time. ETS TOEFL Researchers were from education research and measurement backgrounds and had no special training in language learning or language testing. Stansfield worked with the ETS researchers to help them to develop proposals to present to the TOEFL Research Committee on topics that he felt were most urgent to address based on the growing body of literature on language testing. He also helped to translate the ideas of ETS statisticians into terms that could be understood by the language testing specialists on the research committee, as well as by ETS test developers.

At ETS, Stansfield was made director of the newly operationalized Test of Spoken English (TSE). During its first year of worldwide operations, the test was taken by only 30 examinees, which generated an internal ETS recommendation that the test be discontinued. However, Stansfield argued to the TOEFL policy council that the operational program should be continued. He predicted in 1981 that the TSE would have 10,000 examinees by 1990. In fact, it reached that number that very year. Stansfield wrote the first TSE Manual, trained raters, personally adjudicated all significant score discrepancies across raters, and produced several ETS research reports on the TSE, several of which resulted in journal publications (see Powers and Stansfield, 1985). He also designed and supervised the development of the Speaking Proficiency English Assessment Kit (SPEAK), for use by universities in testing foreign applicants for teaching assistantships on campus. SPEAK continues to be used, over 30 years later.

In 1981, Stansfield was also given responsibility for another newly developed test, the Secondary Level English Proficiency (SLEP) test, following its first year of operations. The SLEP situation was identical to that of the TSE. Stansfield saw that the SLEP could be successful as an off-the-shelf test for use in US public schools. At the time, ETS had little experience with off-the-shelf tests and was lukewarm to continuing any type of SLEP program. However, again Stansfield gained the support of the TOEFL policy council. Stansfield personally took charge of marketing the SLEP and published on it as well (Stansfield, 1984). The SLEP continues to be sold by ETS today and a number of new forms have been developed.

Stansfield's first year at ETS was also the year of publication of what turned out to be a very influential paper by Canale and Swain (1981). The Canale and Swain model of communicative competence included components of sociolinguistic competence and strategic competence, as well as the traditional grammatical competence, and thus helped the language testing field move beyond the more simplistic, discrete-point model that had been dominant since the 1960s. At ETS, however, this new model was not automatically accepted, and Stansfield had to serve as an agent for change. A major example of Stansfield's influence was his advocacy for adding an essay to the TOEFL. The TOEFL had always been made up entirely of multiple-choice items, and previous experience with a writing sample requirement for the SAT had convinced ETS psychometricians that the associated reliability problems outweighed any validity benefits claimed by a free response format.

The skepticism of many of his colleagues notwithstanding, Stansfield presented a proposal to the TOEFL policy council to add a writing sample to the TOEFL. Stansfield argued that the bleak consequences of staying with an exclusively multiple-choice model were that the TOEFL would be perceived as being outdated in terms of its design, and that the prestige of the program would suffer serious decline. Fortunately, the TOEFL policy council agreed.

The next steps in the development of what became the Test of Written English (TWE) were to do a survey of the types of writing tasks that were typical in universities, to write prompts based on those task types, to field-test those prompts, and to create a scoring

rubric with associated scoring procedures. Three task types were selected: compare and contrast, take a position, and describe and interpret a chart or graph. The accepted holistic scoring approach at the time was to divide a sample of examinee papers by topic and to write a few sentences describing the different levels of competence they exhibited, thereby creating a rubric for each topic. This was the part that bothered Stansfield. He felt that a topic-based rubric said nothing about overall writing ability. He argued persistently for the development of a "cross-topic rubric," an idea that was not a part of the literature on holistic scoring and considered unrealistic at the time. However, the efforts that went into the development and extensive trialing of the cross-topic rubric paid off (Stansfield, 1986). After the first operational administration of the TWE, ETS psychometricians and writing specialists were surprised by the significantly higher-than-normal reliability produced by the new cross-topic rubric. After subsequent administrations showed equal or even higher reliability, the cross-topic approach to developing a holistic scoring guide became standard in writing assessment and continues to be so today. The TWE, whose development and operationalization Stansfield directed, became a valuable complement to the TOEFL. At the time he left ETS, he was developing a long-term research agenda for the TWE (Stansfield & Ross, 1988).

At the Center for Applied Linguistics (1986–94)

In 1986, Stansfield left ETS to begin a language testing unit at the Center for Applied Linguistics (CAL). Whereas Stansfield's position at ETS had allowed him to apply his ESL background to work on important English language tests, his position as director of the ERIC Clearinghouse on Languages and Linguistics at the Center for Applied Linguistics afforded him the opportunity to return to non-English languages, and thus to make use of his training in Spanish and bilingual education. He quickly established a testing unit at CAL. One of his main accomplishments was to develop a set of tests that employed a format that would facilitate moving proficiency testing from the government into academia. The two-on-one oral proficiency interview had worked well in US government language programs since the 1950s, but a more practical approach was needed if oral proficiency testing was to be conducted at colleges and universities nationwide. The simulated oral proficiency interview (SOPI) was created for this purpose. Like the TSE, it made use of prerecorded, contextualized prompts, and thereby eliminated the need for interviewers and the associated expense and difficulties of training them. The SOPIs could also be scored on the American Council on the Teaching of Foreign Languages (ACTFL) Proficiency Guidelines.

His work on the SOPIs followed up on John Clark's success in obtaining high correlations between the Chinese Speaking Test (which also employed a semi-direct format) and live interviews with the same candidates. During his first two years at CAL, Stansfield replicated Clark's success with diverse languages (Portuguese, Indonesian, Japanese, and Hebrew). As in the case of SPEAK, the idea was to create a test that an institution could purchase and administer by training their own raters. This led to the development of "rater training kits" that included training materials that explained the test format and scale. The kits also included recordings of "benchmark" samples at each level on the scale along with "justifications" that explained why a particular sample had a particular rating, and not a lower or higher one. He then created enhanced SOPIs in other languages, including the commonly taught languages, such as French, German, and Spanish. In addition, a special form of the SOPI was also developed for the specific purpose of testing candidates for Spanish, French, and bilingual education teacher certification in Texas. The tests Stansfield created and subsequent forms were used for 20 years in Texas.

President of Second Language Testing, Inc (1994–present)

Stansfield left CAL in 1994 to start SLTI. It is unique in its focus on test translation and language test development. Most companies do not limit themselves to one subject area such as language, and they provide full services in the sense of administering and scoring tests as well as developing them. SLTI's niche is to develop tests, language tests only, and to do any needed, related research such as validation and standard setting, and then turn those tests over to the organizations that commissioned them.

Just after leaving his position at CAL, Stansfield received a Mellon Fellowship to study municipal, state, and federal tests for court interpreters. He was also contracted separately to evaluate the Federal Court Certification Exam (FCICE) and to suggest a multiyear program of improvements. These experiences allowed him to utilize two parts of his background that he especially enjoyed: Spanish, and the testing of translators and interpreters. His expertise in interpreter testing grew, as did his reputation in this area. About five years later, in 2001, his company SLTI received a contract to modify the FCICE (Spanish-English screening test), and has continued to create new forms of that test ever since. In recent years SLTI has expanded into developing tests for medical interpreters and for military translators and interpreters. SLTI has also developed listening-summary translation examinations for the US government in Southern Min, Farsi, and five dialects of Arabic.

After creating SLTI, Stansfield also obtained the rights to the Modern Language Aptitude Test (MLAT), the Modern Language Aptitude Test-Elementary (MLAT-E), and the Pimsleur Language Aptitude Battery (PLAB). He formed the Second Language Testing Foundation, a not-for-profit entity to publish these tests and ensure that they would continue to be available. Work related to these tests has included the development of a model for adapting existing aptitude tests (which are mainly designed for persons whose first language is English) to speakers of other languages. A version of the MLAT-E was developed and validated within this model, the Modern Language Aptitude Test-Elementary Spanish (MLAT-ES), or which is also known by its Spanish title, *Prueba de Aptitud para Lenguas Extranjeras*, abbreviated PALE. SLTI also continues work in aptitude testing, and has developed multiple new forms of the US government's defense language aptitude battery as well as multiple forms of a DLAB screening test, the Pre-DLAB.

One of SLTI's current projects is to assist tribes in developing tests of Native American languages under a contract with the Bureau of Indian Education. SLTI is providing technical assistance to the Navajo, the Sioux, Miccosukee, Cherokee, Laguna Pueblo, and Bug-O-Nay-Ge-Shig tribes. The project has already produced an annotated bibliography and a review of the literature on the testing of indigenous languages around the world (Haynes, Stansfield, Gnyra, Schlieff, & Anderson, 2011).

In February 2011, SLTI became a wholly owned subsidiary of Berlitz Languages Inc. As of this writing, Stansfield remains president of SLTI, which continues to make language tests for a variety of clients, including US Government agencies, large testing companies, large private corporations, and educational organizations.

Summary

There are a set of prominent threads that run through Stansfield's long, productive, and ongoing career: his continued interest in the testing needs of foreign language, ESL, and bilingual educators, his involvement in aptitude testing, his work in translation and interpretation, and a special knack for successfully collaborating with different types of organizations. He has worked with private companies large and small, government agencies, K-12 educators and academics while maintaining an active interest in entrepreneurship

and innovation and a concern for the development of the language testing profession. In all these areas, Stansfield is highly respected for his productivity and leadership.

Statistical Analysis of Test Results

ANTONY J. KUNNAN AND NATHAN T. CARR

Introduction

Statistical analysis of test results provides information to test developers and users that can be used as evidence to build an overall validity argument which supports links between the observations of performance on language tests to score interpretations, and score-based decisions (Kane, 1992, 2006; Xi, 2008). The choice of which statistical analyses to perform, and their interpretation, depend in part on whether the test results to be analyzed are from a norm-referenced test (NRT) or a criterion-referenced test (CRT). In the former, a test taker's performance is compared to other test takers' performances who took the same test; while in the latter approach, a test taker's performance is interpreted with reference to a set of performance criteria (such as standards or mastery levels with respect to test content) previously set by the test developer or a stakeholder. Sometimes, a test is designed to be used as both an NRT and a CRT, but this fact is also relevant to statistical analysis.

Statistical Analyses

Statistical analyses provide a means of systematically summarizing examinees' performance on a test to provide information about both the examinees and the test as a measure for a particular group of examinees. The latter use of statistical analysis is the main focus here—the use of statistics for evaluating how good a test is for its intended purpose. The statistical procedures are grouped according to four of the perspectives on test quality, which can be used in demonstrating the validity of test interpretation and use: evaluation, generalization, explanation, and utilization (following Bachman, 2005, and Chapelle, Enright, & Jamieson, 2008).

Evaluation

Evaluation issues pertain to the defensibility of the manner in which examinees' performance is summarized into test scores. Examinees' scores are used to reflect their performance and therefore the link between performance and score needs to be supported in several ways.

First, it is important to understand the distributions of the test takers. Statistical analysis can reveal the distributions through calculation of the following: mean, median (used for small samples), mode, and standard deviation. These results will provide information on the examinees' scores in terms of the average score (mean), its mid-point (median), most frequently occurring score (mode), and the overall variation from the average (standard deviation). For large groups and in contexts where further statistical analysis is planned, skewness (scores bunching toward to the right, center, or left of a score distribution shape) and kurtosis (whether the scores are peaked or flat in terms of the score distribution shape) would also be examined. Overall, these descriptive statistics inform the test researcher or classroom teacher about how a test-taking sample performed on a test. (See Carr, 2008, for a more complete discussion.)

2 STATISTICAL ANALYSIS OF TEST RESULTS

Second, we need to evaluate the statistical characteristics of items, tasks, and tests. One approach in assessing the quality of test items and tasks or improving their overall quality is to pilot (or pretest) the test items or tasks. The data obtained need to be scored and coded to provide a database for statistical analyses. Statistical analyses can then be conducted with a view to evaluating whether the items and tasks behave as intended. The identification of which items are appropriate or problematic is accomplished through *item analysis*, consisting of analysis of *item difficulty*, *item discrimination*, and *distractor analysis*.

Item difficulty is most commonly estimated by using *item facility* (IF; also commonly referred to as p), the proportion of test takers who responded to a test item correctly. In the case of NRT, ideally, items will have an IF near .50; that is, half of the test takers will answer each item correctly. The item will then provide the maximum information for the largest group of test takers (i.e., those in the middle ability range, if scores are in fact distributed normally, as they should be on an NRT). Allen and Yen (1978) point out, however, that in practice, items ranging between .30 and .70 are generally acceptable. Items outside this range are deemed to be too difficult or too easy, respectively. On the other hand, in CRT we hope that 50% of the test takers whose ability level is at the cut score will answer a given item correctly. In practice, unfortunately, this is a very difficult proposition to manage; as a result, in CRT item analysis, IF is usually only reported for general information, and to assist with the interpretation of discrimination and distractor analysis results.

Item discrimination can be analyzed following two approaches for both NRT and CRT: correlational and subtractive. In NRT, the correlational approach uses the point-biserial ($pb(r)$ or r_{p-bis}) correlation coefficient between each item and the total score on that section of the test. If the test is one homogeneous whole (e.g., composed entirely of discrete-point grammar items, rather than separate grammar and vocabulary sections), of course, the items should be correlated with total test score. The correlational index is interpreted as the relationship between performance on the item and on the section or test as a whole; it is therefore simply an item-total correlation. The subtractive NRT index is the upper-lower discrimination (*item discrimination*, abbreviated ID or ID_{UL}). This is the difference between the IF for high-scoring and low-scoring test takers; these two groups are usually defined as the top and bottom 25%, 27%, or thirds of the test takers taking the test. One drawback to using ID is that it ignores the performance of all the test takers in the middle. Thus, when sample sizes are large enough ($n > 35$, perhaps), the point-biserial may be preferable.

In CRT, the correlational approach uses the ϕ (phi; also referred to as item ϕ) correlation coefficient between each item and mastery/nonmastery classification (mastery = 1, nonmastery = 0). Items should, of course, be correlated with section mastery/nonmastery when there are distinct sections. The most commonly used CRT subtractive approach is the B-index, which is calculated by subtracting the IF for all test takers who failed the test (nonmasters) from that of test takers who passed the test (masters). Another less commonly used subtractive CRT index is the difference index (DI). This requires administering a test twice, either to the same group before and after instruction, or to one group of test takers who are presumed to have mastered something and another group who presumably have not (e.g., test takers in two levels of a language program). Like the B-index, it is calculated by subtracting the IF values for the two groups. Both item ϕ and the B-index are cut-score dependent; that is, as with ϕ lambda ($\Phi(\lambda)$), if there are multiple cut scores, they must be reported for each cut score. Similarly, when more than two groups are used for the DI (as in a placement test), it must be reported for each pair of adjacent groups (levels one and two, levels two and three, and so on).

When interpreting discrimination indices for an NRT or CRT, the same rules of thumb apply. For the point-biserial or item ϕ , ideally, items should have discrimination values of .30 or above. For ID, the B-index, and the DI, values should be .40 and above. These

values are what is typically expected in the context of professional item development for high-stakes testing, though; in the case of locally developed tests, particularly those to be used for classroom testing, it is often necessary to accept lower values. These rules of thumb—both for discrimination and for difficulty—are *not* absolutes, and it is important to keep in mind that these analyses matter most when it is necessary to improve a test with poor internal consistency. When a test already has high reliability or dependability, it is probably only necessary to worry about the worst items, unless one is hoping to shorten the test.
